The largest order statistics for the inradius in an isotropic STIT tessellation

Nicolas Chenavier [*]and Werner Nagel[†]

28th December 2018

Abstract

A planar stationary and isotropic STIT tessellation at time $t > 0$ is observed in the window $W_\rho = t^{-1}\sqrt{\pi \rho} \cdot [-\frac{1}{2}, \frac{1}{2}]^2$, for $\rho > 0$. With each cell of the tessellation, we associate the inradius, which is the radius of the largest disk contained in the cell. Using the Chen-Stein method, we compute the limit distributions of the largest order statistics for the inradii of all cells whose nuclei are contained in W_ρ as ρ goes to infinity.

1 Introduction

A planar tessellation T in $\mathbb{R}^2$ is a countable collection of non-empty convex polygons, called *cells*, with disjoint interiors which subdivides the plane $\mathbb{R}^2$, and such that the number of cells intersecting any bounded subset of $\mathbb{R}^2$ is finite. Let $\mathcal{T}$ be the set of planar tessellations, endowed with the usual σ-field, see p. 8. A random planar tessellation is a random variable with values in $\mathcal{T}$. For a complete account on random planar tessellations, and more generally random tessellations in a d-dimensional Euclidean space, $d \geq 2$, we refer to the books [18, 20].

One of the important models is the STIT (STable under ITerations) tessellation. This random tessellation was introduced in [15] and has potential applications for the modeling of crack patterns or of fracture structures, such as the so-called craquelée on pottery surfaces, drying films of colloidal particles, or structures observed in geology [7, 13]. There are quite a few theoretical results for STIT tessellations, including ergodicity [8], mixing properties [6], computations of distributions [12] and a Mecke-type formula [14].

Let $\mathbf{Y} = (Y_t, \, t > 0)$ be a STIT tessellation process in the Euclidean plane $\mathbb{R}^2$, where for any $t > 0$ the tessellation Y_t is spatially stationary and isotropic. The Euclidean plane $\mathbb{R}^2$ is endowed with its Euclidean norm $||\cdot||$. Let $t > 0$ be fixed. With each cell $z \in Y_t$ we associate the incenter $c(z)$ of z, defined as the center of the largest disk included in z. For each cell the incenter exists and is almost surely unique. Now, let B be

a Borel subset in $\mathbb{R}^2$ with area $a(B) \in (0, \infty)$. The *cell intensity* γ_t of Y_t is defined as the mean number of cells per unit area, i.e.

$$\gamma_t = \frac{1}{a(B)} \, \mathbb{E}\left[\#\{z \in Y_t : c(z) \in B\} \right].$$

Because a STIT tessellation is stationary, the intensity is in fact independent of the Borel subset $B \subset \mathbb{R}^2$. In the present paper, the STIT tessellation Y_t is scaled in such a way that $\gamma_t = \frac{t^2}{\pi}$. The *typical cell* is a random polygon $\mathcal{Z}$ whose distribution is given by

$$\mathbb{E}\left[g(\mathcal{Z}) \right] = \frac{1}{\gamma_t \, a(B)} \, \mathbb{E}\left[\sum_{z \in Y_t : c(z) \in B} g(z - c(z)) \right], \qquad (1.1)$$

for all nonnegative measurable functions $g : \mathcal{K}_0 \to \mathbb{R}$ on the set $\mathcal{K}_0$ of centered convex bodies, i.e. all non-empty convex compact sets $K \subset \mathbb{R}^2$ with $c(K) = 0$, endowed with the Hausdorff topology. (For those random tessellations for which the incenters of cells are not a.s. unique, choose another center function c for the cells).

It is notable that the distribution of the typical cell in a STIT tessellation is the same as in a stationary Poisson line tessellation with corresponding parameters [15], i.e. in our case, the stationary and isotropic Poisson line tessellation with the same cell number intensity γ_t.

In the present paper, as a first approach on extremal properties of a STIT tessellation, we study the largest order statistics for the inradius. The inradius is one of the rare geometric characteristics for which the distribution can be made explicit. Before stating our main theorem, we introduce some notation. For each cell $z \in Y_t$, we denote by $R(z)$ the *inradius* of z, i.e. the radius of the largest disk included in the cell z. It is known that the inradius of the typical cell of Y_t has an exponential distribution with parameter $2t$ (Lemma 3 in [15]), i.e.

$$\mathbb{P}\left(R(\mathcal{Z}) > v \right) = e^{-2tv}, \quad v \geq 0. \qquad (1.2)$$

Consider the family $W_\rho = t^{-1}\sqrt{\pi \rho} \cdot [-\frac{1}{2}, \frac{1}{2}]^2$, $\rho > 0$, of squares which we refer to as windows. Now, for each threshold $v \geq 0$, let $N_{W_\rho}(v)$ be the number of cells with incenters in W_ρ and with inradii larger than v, i.e.

$$N_{W_\rho}(v) := \sum_{z \in Y_t : c(z) \in W_\rho} \mathbf{1}_{R(z) > v} \,. \qquad (1.3)$$

The cells with inradius exceeding v are referred to as *exceedances*. According to (1.1), the mean number of exceedances is given by $\mathbb{E}\left[N_{W_\rho}(v) \right] = \gamma_t \, t^{-2} \pi \rho \, \mathbb{P}\left(R(\mathcal{Z}) > v \right)$.

In this paper, we provide a Poisson approximation of the number of exceedances when the size ρ of the window goes to infinity. The underlying threshold which we consider has to depend on ρ. To define it, let $\tau > 0$ be a fixed value. The threshold is chosen as a function v_ρ, $\rho > 0$, in such a way that the mean number of exceedances equals τ, i.e.

$$\mathbb{E}\left[N_{W_\rho}(v_\rho) \right] = \gamma_t \, t^{-2} \pi \rho \, \mathbb{P}\left(R(\mathcal{Z}) > v_\rho \right) = \tau. \qquad (1.4)$$

Thus, the threshold is chosen as:

$$v_\rho := v_\rho(\tau) = \frac{1}{2t}(\log \rho - \log \tau). \qquad (1.5)$$

We consider the convergence of distributions with respect to the total variation. In the particular case of two random variables X and Z with values in $\mathbb{N}_0 = \{0, 1, 2, \ldots\}$, we recall that the total variation distance is given by

$$d_{TV}(X, Z) := 2 \sup_{A \subset \mathbb{N}_0} |\mathbb{P}\left(X \in A \right) - \mathbb{P}\left(Z \in A \right)|.$$

2

We are now prepared to state our main result.

Theorem 1.1. *Let Y_t be a stationary and isotropic STIT tessellation in $\mathbb{R}^2$ at time $t > 0$ with cell number intensity $\gamma_t = \frac{t^2}{\pi}$. Let $\tau > 0$ be fixed. Let v_ρ be as in (1.5) and $N_{W_\rho}(v_\rho)$ as in (1.3). Furthermore, let Z be a random variable with a Poisson distribution with parameter τ. Then*

$$d_{TV}(N_{W_\rho}(v_\rho), Z) \underset{\rho \to \infty}{\longrightarrow} 0. \tag{1.6}$$

In particular, for each nonnegative integer r we have

$$\mathbb{P}\left(N_{W_\rho}(v_\rho) = r\right) \underset{\rho \to \infty}{\longrightarrow} e^{-\tau} \cdot \frac{\tau^r}{r!}.$$

Now, for each $k \geq 1$, let $M_{W_\rho}^{(k)}$ be the k-th largest value of the inradius over all cells with incenter in W_ρ, and set $M_{W_\rho}^{(k)} = 0$ if the number of such cells is smaller than k. The random variables $M_{W_\rho}^{(k)}$ are referred to as the *order statistics*. In particular, when $k = 1$, the random variable $M_{W_\rho}^{(1)}$ is the maximum of the inradii over all cells with incenter in W_ρ. As a corollary of Theorem 1.1, we obtain the following result.

Corollary 1.2. *With the same assumptions as in Theorem 1.1 we have for all $k \geq 1$*

$$\mathbb{P}\left(M_{W_\rho}^{(k)} \leq v_\rho\right) \underset{\rho \to \infty}{\longrightarrow} \sum_{r=0}^{k-1} e^{-\tau} \cdot \frac{\tau^r}{r!}.$$

This result is a direct consequence of Theorem 1.1 and of the fact that $M_{W_\rho}^{(k)} \leq v_\rho$ if and only if $N_{W_\rho}(v_\rho) \leq k - 1$. According to Corollary 1.2, the maximum of inradii belongs to the domain of attraction of a Gumbel distribution. Indeed, by taking $\tau = e^{-u}$ and $k = 1$, we obtain

$$\mathbb{P}\left(M_{W_\rho}^{(1)} \leq \frac{1}{2t}\log\rho + \frac{1}{2t}u\right) \underset{\rho \to \infty}{\longrightarrow} e^{-e^{-u}},$$

with $u \in \mathbb{R}$. This limit result is classical in Extreme Value Theory according to Gnedenko's theorem (see e.g. Theorem 1.1.3 in [5]).

It is noticeable that the largest order statistics of the inradius in a STIT tessellation have asymptotically the same distribution as the order statistics of the inradius in a Poisson line tessellation with the same intensity (see Theorem 1.1 (ii) in [4]). This fact is not surprising in the sense that the typical cell of a STIT tessellation has the same distribution as the typical cell of a stationary Poisson line tessellation. However, Theorem 1.1 and Corollary 1.2 of the present paper are not consequences of Theorem 1.1 (ii) of [4]. Indeed, dealing with extremes requires a specific treatment of correlations between cells and a mixing condition: the fact that two random tessellations have the same typical cell is not sufficient to ensure that the extremes have the same behaviour. Although Theorem 1.1 and Theorem 1.1 (ii) of [4] are both based on Poisson approximation, the methods which are used are different. In [4], the Poisson approximation is derived from the method of moments whereas, in our paper, this is based on the Chen-Stein method. We think that the method of moments is not suitable for STIT tessellations because they are based on a time process. A method similar to the one used in [4] should lead to very technical computations in the context of STIT tessellation.

Our paper complements [2, 3] where Poisson-Voronoi tessellations are treated. However, although Theorem 1 in [3] is a general result on extremes for random tessellations, the conditions of this theorem are too restrictive

to be applied to STIT tessellations. Indeed, Theorem 1 in [3] needs a so-called (FRC) condition which is not satisfied for a STIT tessellation.

Our paper is organized as follows. In Section 2, we set up the notation, formally introduce the STIT tessellation processes and recall several known results which will be used in the proof of Theorem 1.1. In Section 3, we state technical results which will be used to prove our main theorem. The proofs of these technical lemmas and of Theorem 1.1 are given in Sections 4 and 5, respectively. In Section 6 we mention some potential extension of our main theorem.

2 Preliminaries

2.1 Notation

By S^1 we denote the unit sphere centered at the origin. For $c \in \mathbb{R}^2$ and $R > 0$, the set $B(c, R)$ denotes the topologically closed (Euclidean) disk with center $c \in \mathbb{R}^2$ and radius $R > 0$. For any subset $B \subset \mathbb{R}^2$, the set B° denotes the interior of B. If B is a Borel subset, we recall that its area is denoted by $a(B)$. Further, $\oplus$ and $\ominus$ denote the Minkowski addition and subtraction of sets, respectively.

We denote by $\mathcal{H}$ the set of all lines in the plane. For any $B \subset \mathbb{R}^2$, we write

$$[B] := \{H \in \mathcal{H} : H \cap B \neq \emptyset\}.$$

By Λ, we denote the measure on the set of lines $\mathcal{H}$ (endowed with the usual σ-algebra, see e.g. [18]), which is invariant under translations and rotations of the plane, with normalization $\Lambda([B(0,1)]) = 2$. In particular, for any convex polygon $z \subset \mathbb{R}^2$, we have $\Lambda([z]) = perimeter(z)/\pi$. We shortly write d$H$ instead of $\Lambda(\mathrm{d}H)$ in integrals over the set of lines. Thus, for all nonnegative measurable functions $f : \mathcal{H} \to \mathbb{R}$, we have:

$$\int_{\mathcal{H}} f(H)\mathrm{d}H = \int_{(0,\infty)} \int_{S^1} f(H(r,u))\mathrm{d}r\, \sigma(\mathrm{d}u), \tag{2.1}$$

where $H(r, u)$ is the line with distance $r > 0$ from the origin and normal direction $u \in S^1$, and where σ is the rotation invariant measure on S^1 with normalization $\sigma(S^1) = 2$.

Given three lines H_1, H_2 and H_3 in general position, we use the notation $H_{1:3} := (H_1, H_2, H_3) \in \mathcal{H}^3$, and we denote by $\Delta(H_{1:3})$ the unique triangle that can be formed by the intersection of halfplanes induced by these lines, and $B(H_{1:3})$, $c(H_{1:3})$, $R(H_{1:3})$ are the incircle, the incenter and the inradius of $\Delta(H_{1:3})$, respectively. In particular, $B(H_{1:3}) = B(c(H_{1:3}), R(H_{1:3}))$. Similarly, if s_1, s_2, s_3 are three linear segments in $\mathbb{R}^2$ in general position, we write $s_{1:3} := (s_1, s_2, s_3)$. Correspondingly, $B(s_{1:3})$, $c(s_{1:3})$, $R(s_{1:3})$ denote the incircle, the incenter and the inradius of the triangle formed by the three lines containing the three segments. With a slight abuse of notation, we also write $\{s_{1:3}\} = \{s_1, s_2, s_3\}$.

Let Y_t be a STIT tessellation at time t. For any Borel subset $B \subset \mathbb{R}^2$ and for any threshold $v \geq 0$, we write

$$M_B = \max_{z \in Y_t : c(z) \in B} R(z) \quad \text{and} \quad N_B(v) = \sum_{z \in Y_t : c(z) \in B} \mathbf{1}_{R(z) > v}. \tag{2.2}$$

This notation $N_B(v)$ is consistent with (1.3).

Moreover, for any finite set A, we denote by $|A|$ the number of elements of A. For any real number x, we denote by $\lfloor x \rfloor$ the integer part of x. Given a probability space $(\Omega, \mathcal{E}, \mathbb{P})$, and two random variables X and Y defined on Ω, the notation $X \stackrel{d}{=} Y$ indicates that X and Y have the same distribution. We write $\mathbb{E}[Y|X]$ for the conditional expectation of Y with respect to X.

4

2.2 The STIT tessellation

The STIT tessellation process in the d-dimensional Euclidean space was first introduced in [15]. Since then, in a series of publications several equivalent descriptions were given. In the present paper we consider planar stationary and isotropic STIT tessellations. Below we give a short reminder for this particular case only.

We start with the construction of a tessellation process $(Y_{t,W}, t \geq 0)$ in a bounded convex polygon W, referred to as a window. All the random variables that we consider are defined on some probability space $(\Omega, \mathcal{E}, \mathbb{P})$. Let $\tau_0, \tau_1, \tau_2, \ldots$ be independent and identically distributed (i.i.d.) random variables, all exponentially distributed with parameter 1.

(i) The initial state of the process is $Y_{0,W} = \{z_1\} := \{W\}$, and the random holding time in this state is $\tau_0/\Lambda([W])$, i.e. it is exponentially distributed with parameter $\Lambda([W])$.

(ii) At the end of the holding time, the window W is divided by a random line H_1 with law $(\Lambda([W]))^{-1}\Lambda(\cdot \cap [W])$. This law is the probability distribution on $[W]$ generated by the restricted and normalized measure Λ. The new state of the STIT process is now $\{z_1, z_2\}$, where $z_1 := W \cap H_1^+$ and $z_2 := W \cap H_1^-$, and H_1^+ and H_1^- are the two closed half-planes generated by H_1. Here it does not play a role which one is the positive or the negative half-plane. The random life times of z_1 and z_2 are $\tau_1/\Lambda([z_1])$ and $\tau_2/\Lambda([z_2])$, respectively.

(iii) Now, inductively, for $t > 0$, assume that $Y_{t,W} = \{z_{i_1}, \ldots, z_{i_n}\}$. The life times of the cells are $\tau_{i_1}/\Lambda([z_{i_1}]), \ldots, \tau_{i_n}/\Lambda([z_{i_n}])$, respectively. At the end of the life time of a cell z_{i_j}, this cell is divided by a random line H_{i_j} with the law $(\Lambda([z_{i_j}]))^{-1}\Lambda(\cdot \cap [z_{i_j}])$, which is a probability distribution on $[z_{i_j}]$. Given the state of the tessellation process at the time of division, this line is conditionally independent from all the other dividing lines used so far. The divided cell z_{i_j} is deleted from the tessellation and is replaced by the two "daughter" cells $z_{i_j} \cap H_{i_j}^+$ and $z_{i_j} \cap H_{i_j}^-$. These cells are endowed with new indexes from $\mathbb{N}$ which are not used before in this process.

An essential property of the construction is that the distribution of the tessellation generated in a window W is spatially consistent in the following sense. If W and W' are two convex polygons with $W \subset W'$ and $Y_{t,W}, Y_{t,W'}$ the respective random tessellations, then $Y_{t,W} \overset{d}{=} Y_{t,W'} \wedge W$ are identically distributed, where

$$Y_{t,W'} \wedge W := \{z \cap W : z \in Y_{t,W}, z \cap W^\circ \neq \emptyset\}$$

is the restriction of $Y_{t,W'}$ to W. This property yields the existence of a stationary random tessellation Y_t of $\mathbb{R}^2$ such that its restriction $Y_t \wedge W$ to any window W has the same distribution as the constructed tessellation $Y_{t,W}$. Since the measure Λ is invariant under rotation with the normalization $\Lambda([B(0,1)]) = 2$, the STIT tessellation Y_t is isotropic and its intensity is $\gamma_t = \frac{t^2}{\pi}$ (see [16]). A "global construction", that does not refer to a bounded window, of the process $(Y_t, t > 0)$ was given in [11], but this is much more involved.

Throughout this paper, we work with the stationary and isotropic STIT tessellation Y_t for some $t > 0$. Notice that a scaling property holds in the sense that

$$t \cdot Y_t := \{t \cdot z : z \in Y_t\} \overset{d}{=} Y_1. \tag{2.3}$$

The important constituents of planar STIT tessellations are the *maximal segments* (also referred to as I-segments), which are those segments generated by the intersection of a cell with its dividing line. In their relative interior, these maximal segments can contain endpoints of other maximal segments which appear later in the process. By m_t we denote the set of all maximal segments of Y_t. The union of the boundaries of the cells, the so-called *skeleton*, is denoted by ∂Y_t. It coincides with the union of all maximal segments.

2.3 Poisson approximation

It is clear that if $X(1), \dots, X(\lfloor \rho \rfloor)$ are independent and identically distributed random variables with the same distribution as the inradius of the typical cell, i.e. with exponential distribution with parameter $2t$, then $\sum_{i=1}^{\lfloor \rho \rfloor} \mathbf{1}_{X(i) > v_\rho}$ converges in total variation to a Poisson random variable with parameter τ, where v_ρ is as in (1.5). Theorem 1.1 establishes the same type of result, excepted that the random variables which we consider consist of a family of inradii of cells which are *not independent.* The main difficulty in our work comes from the dependence between the cells, and consists in showing that the number of exceedances $N_{W_\rho}(v_\rho)$ has the same behaviour *as if* we consider $\lfloor \rho \rfloor$ independent random variables, with the same distribution as the inradius of the typical cell.

In the same spirit as in [3], the main idea to derive a Poisson approximation of $N_{W_\rho}(v_\rho)$ is to apply a result due to Arratia, Goldstein and Gordon [1]. Their result is based on the Chen-Stein method and gives an upper bound for the total variation distance between the distribution of a sum of Bernoulli random variables, and a Poisson distribution.

Let us recall the framework of their result. For an arbitrary index set I, and for $i \in I$, let X_i be a Bernoulli random variable with $p_i = \mathbb{P}(X_i = 1) = 1 - \mathbb{P}(X_i = 0)$. For each $i, j \in I$, we write $p_{ij} = \mathbb{E}[X_i X_j]$. Further, we let

$$X := \sum_{i \in I} X_i \quad \text{and} \quad \lambda := \mathbb{E}[X] = \sum_{i \in I} p_i, \quad \text{and assume that} \quad 0 < \lambda < \infty.$$

For each $i \in I$, fix a "neighborhood" $B_i \subset I$ with $i \in B_i$, and define

$$b_1 := \sum_{i \in I} \sum_{j \in B_i} p_i p_j, \quad b_2 := \sum_{i \in I} \sum_{i \neq j \in B_i} p_{ij}, \quad b_3 := \sum_{i \in I} \mathbb{E}\left[\left|\mathbb{E}\left[X_i - p_i \middle| \sum_{j \in I \setminus B_i} X_j\right]\right|\right].$$

Roughly, b_1 measures the neighborhood size, b_2 measures the expected number of neighbors of a given occurrence and b_3 measures the dependence between an event and the number of occurrences outside its neighborhood. We are now prepared to state a result on Poisson approximation (see Theorem 1 of [1]).

Proposition 2.1. *(Arratia, Goldstein, Gordon) Let Z be a Poisson random variable with mean $\lambda \in (0, \infty)$. With the above notation and the assumptions, we have*

$$d_{TV}(X, Z) \leq 2\left((b_1 + b_2) \cdot \frac{1 - e^{-\lambda}}{\lambda} + b_3 \cdot \min\{1, 1.4\,\lambda^{-1/2}\}\right).$$

3 Technical results

First notice, that for arbitrary $t > 0$ the scaling property (2.3) of the STIT tessellation process yields that

$$\sum_{z \in Y_t : c(z) \in W_\rho} \mathbf{1}_{R(z) > v_\rho} \overset{d}{=} \sum_{z \in Y_1 : c(z) \in t\,W_\rho} \mathbf{1}_{R(z) > t\,v_\rho}.$$

Hence, it is sufficient to prove Theorem 1.1 for $t = 1$, which will simplify the formulas. From now on, we will always set $t = 1$, with the only exception in Lemma 3.4.

We adapt several arguments contained in [3] to our context. The difficulty compared to [3] comes from the fact that a STIT tessellation only has a β-mixing property, see [10], whereas the tessellations considered in [3] satisfy a finite range condition. The main idea is to subdivide the window W_ρ into small squares to be

in the framework of Proposition 2.1. We first introduce this subdivision. Then we establish several technical lemmas which deal with an asymptotic property and a local property, respectively. These technical lemmas will be applied to derive Theorem 1.1 in the next section.

3.1 A subdivision of the window

Recall that $W_\rho = \sqrt{\pi \rho} \cdot [-\frac{1}{2}, \frac{1}{2}]^2$ if $t = 1$. When $\rho > e$, we subdivide the window W_ρ into a set V of sub-squares of equal size, where the number of these sub-squares is

$$|V| = \left(\left\lfloor \sqrt{\frac{\pi \rho}{\log \log \rho}} \right\rfloor \right)^2. \tag{3.1}$$

The sub-squares are indexed by $\mathbf{i} := (i_1, i_2) \in \left[1, \sqrt{|V|} \right]^2$, analogously to the order of indexing the elements of a matrix. With a slight abuse of notation, we identify a square with its index.

In our proof we will often use the fact that there exists a $\rho_0(\tau)$ such that, for all $\rho > \rho_0(\tau)$, we have

$$v_\rho > \sqrt{2} \frac{\sqrt{\pi \rho}}{\left\lfloor \sqrt{\frac{\pi \rho}{\log \log \rho}} \right\rfloor}, \tag{3.2}$$

where $v_\rho = v_\rho(\tau)$ is as in (1.5). The right-hand side in the above equation is the length of the diagonal of a sub-square $\mathbf{i}$. Thus, for $\rho > \rho_0(\tau)$, there can be at most one incircle with center in $\mathbf{i}$ and radius larger than v_ρ.

The distance between sub-squares $\mathbf{i}$ and $\mathbf{j}$ is defined as $d(\mathbf{i}, \mathbf{j}) := \max_{1 \leq s \leq 2} |i_s - j_s|$. For $\mathbf{i} \in V$ and $r > 0$ define the r-neighborhood of $\mathbf{i}$ as

$$S(\mathbf{i}, r) := \{\mathbf{j} \in V : d(\mathbf{i}, \mathbf{j}) \leq r\}. \tag{3.3}$$

The main idea to prove Theorem 1.1 is to apply Proposition 2.1 with $X_{\mathbf{i}} := \mathbf{1}_{M_{\mathbf{i}} > v_\rho}$. We recall that $M_{\mathbf{i}}$ is the maximum of inradii over all cells with nucleus in $\mathbf{i}$, i.e. $M_{\mathbf{i}} = \max_{z \in Y_1 : c(z) \in \mathbf{i}} R(z)$. The sets B_i of Proposition 2.1 are replaced by the neighborhoods $S(\mathbf{i}, \rho^{\beta/2})$ for some $\beta \in (0, 1)$. Furthermore, for all sub-squares $\mathbf{i}, \mathbf{j} \in V$, we denote

$$p_{\mathbf{i}} := \mathbb{P}\left(M_{\mathbf{i}} > v_\rho \right) \quad \text{and} \quad p_{\mathbf{ij}} := \mathbb{P}\left(M_{\mathbf{i}} > v_\rho, M_{\mathbf{j}} > v_\rho \right).$$

We also let

$$b_1 := \sum_{\mathbf{i} \in V} \sum_{\mathbf{j} \in S(\mathbf{i}, \rho^{\beta/2})} p_{\mathbf{i}} p_{\mathbf{j}}, \quad b_2 := \sum_{\mathbf{i} \in V} \sum_{\mathbf{i} \neq \mathbf{j} \in S(\mathbf{i}, \rho^{\beta/2})} p_{\mathbf{ij}}, \quad b_3 := \sum_{\mathbf{i} \in V} \mathbb{E}\left[\left| \mathbb{P}\left(M_{\mathbf{i}} > v_\rho \,\middle|\, \sum_{\mathbf{j} \notin S(\mathbf{i}, \rho^{\beta/2})} \mathbf{1}_{M_{\mathbf{j}} > v_\rho} \right) - p_{\mathbf{i}} \right| \right]. \tag{3.4}$$

In Section 5, we will show that b_1, b_2 and b_3 converge to 0 as ρ goes to infinity, and thus an application of Proposition 2.1 yields the proof of Theorem 1.1.

3.2 Technical lemmas

We start with some technical lemmas which will be used to prove that b_2 and b_3 converge to 0 as ρ goes to infinity.

7

Lemmas concerning an upper bound for b_2   The arguments showing that b_2 converges to 0 are mainly inspired by [4], and they rely on a "local condition", i.e. on an upper bound for the probability that the incircles of two cells with centers in a short distance simultaneously exceed the threshold v_ρ. The following lemma provides an upper bound of the probability that ∂Y_1 does not intersect a union of disks, and it is an adaptation of Lemma 4.4 of [4] in the context of STIT tessellations.

Lemma 3.1. *There exists a constant $\eta > 0$ such that for all pairs of disks $B_1 = B(c_1, r)$ and $B_2 = B(c_2, r)$ with the same radius $r > 0$ and with centers $c_1, c_2 \in \mathbb{R}^2$ satisfying $\|c_1 - c_2\| \geq 2r$ we have*

$$\mathbb{P}\left(\partial Y_1 \cap (B_1 \cup B_2) = \emptyset \right) \leq \eta \cdot e^{-2(1 + \frac{2}{\pi})r}.$$

The proof is given in Subsection 4. This lemma is one of the key ingredients to prove that b_2 converges to 0. Indeed, together with some non-trivial computations which are performed in Section 5, Lemma 3.1 yields that, with high probability, the inradii of two cells which are close enough (in the sense that the incenter of one of them belongs to some sub-square $\mathbf{i}$, and the other belongs to some sub-square $\mathbf{j} \in S(\mathbf{i}, \rho^\beta)$) cannot simultaneously exceed the threshold v_ρ.

The following lemmas are adaptations of Lemma A.1 (i) and Lemma A.1 (ii) in [4] respectively.

Lemma 3.2. *There exists a constant $\eta > 0$ such that for all lines $H_1 \in \mathcal{H}$ and all $R > 0$ we have*

$$G(H_1) := \int_{\mathcal{H}^2} \mathbf{1}_{c(H_{1:3}) \in B(0,R)} \, \mathrm{d}H_{2:3} \leq \eta \, R^2.$$

The following result is similar to Lemma 3.2, but this time two lines are fixed.

Lemma 3.3. *There exists a constant $\eta > 0$ such that for all pairs of lines $H_1, H_2 \in \mathcal{H}$ and all $R > 0$ we have*

$$G(H_1, H_2) := \int_{\mathcal{H}} \mathbf{1}_{c(H_{1:3}) \in B(0,R)} \, \mathrm{d}H_3 \leq \eta \, R.$$

Lemmas concerning an upper bound for b_3   The arguments showing that b_3 converges to 0 are mainly inspired by [10]. The key argument is a mixing property of the STIT tessellations. However, the general upper bound for the β-mixing coefficient provided in [10] is not sufficient for our purposes. Therefore, a more specific treatment of rare events is developed.

To do it, let $\mathcal{C}$ denote the set of all compact convex subsets of $\mathbb{R}^2$. Furthermore, let $\sigma(\mathcal{I})$ be the σ-algebra generated by the family $\mathcal{I}$ of sets. Denote by $\mathcal{T}$ the set of all tessellations of $\mathbb{R}^2$. We endow $\mathcal{T}$ with the Borel σ-algebra $\mathcal{B}(\mathcal{T})$ of the Fell topology, namely

$$\mathcal{B}(\mathcal{T}) := \sigma\left(\{\{T \in \mathcal{T} : \partial T \cap C = \emptyset\} : C \in \mathcal{C}\} \right).$$

Moreover, for some compact convex set $K \subset \mathbb{R}^2$, we define

$$\mathcal{B}(\mathcal{T}_K) := \sigma\left(\{\{T \in \mathcal{T} : \partial T \cap C = \emptyset\} : C \subset K, \, C \in \mathcal{C}\} \right),$$
$$\mathcal{B}(\mathcal{T}_{K^c}) := \sigma\left(\{\{T \in \mathcal{T} : \partial T \cap C = \emptyset\} : C \subset K^c, \, C \in \mathcal{C}\} \right).$$

Let K', K be two convex polygons such that $0 \in K' \subset K$. In [9] the concept of *encapsulation* was introduced. It means that there is a state of the STIT process $\mathbf{Y} = (Y_t, t > 0)$ such that all facets of K' are separated from the facets of K by facets of the tessellation before the interior of K' is divided by a facet of

the tessellation. Formally, denoting the 0-cell by C_t^0, i.e. the cell of Y_t that contains the origin, we define the encapsulation time as

$$S(K, K') := \inf\{t > 0 : K' \subset C_t^0 \subset K^\circ\},$$

with the convention $\inf \emptyset = \infty$. The following lemma is an adaptation of Lemma 6.4 in [10].

Lemma 3.4. *Let $\mathbf{Y} = (Y_t, t > 0)$ be a STIT process. Let $0 \in K' \subset K$ be two convex polygons, $\mathcal{E} \in \mathcal{B}(\mathcal{T}_{K^c})$ and $\mathcal{A} \in \mathcal{B}(\mathcal{T}_{K'})$. Then for all $0 < s < t$ we have*

$$|\mathbb{P}(Y_t \in \mathcal{E} | Y_t \in \mathcal{A}) - \mathbb{P}(Y_t \in \mathcal{E})|$$

$$\leq \mathbb{P}(Y_t \in \mathcal{E} | Y_t \in \mathcal{A}) - \frac{\mathbb{P}(Y_{t-s} \in \mathcal{A})}{\mathbb{P}(Y_t \in \mathcal{A})} \cdot \mathbb{P}(Y_t \in \mathcal{E}, S(K, K') < s, Y_s \wedge K' = K')$$

$$+ \left| \frac{\mathbb{P}(Y_{t-s} \in \mathcal{A})}{\mathbb{P}(Y_t \in \mathcal{A})} - 1 \right| \mathbb{P}(Y_t \in \mathcal{E}) + \frac{\mathbb{P}(Y_{t-s} \in \mathcal{A})}{\mathbb{P}(Y_t \in \mathcal{A})} \cdot \mathbb{P}(\{Y_t \in \mathcal{E}\} \cap \{S(K, K') < s, Y_s \wedge K' = K'\}^c).$$

Now we construct particular squares $K' \subset K$ which are tailored for our purposes. Recall that V is a subdivision of the window W_ρ, $\rho > 0$, into small squares, and that $S(\mathbf{i}, r)$ denotes the r-neighborhood of a square $\mathbf{i} \in V$ (see Section 3.1). By $\mathbf{S}_0$ we denote the square centered at the origin with side length $2v_\rho^2$, and

$$C(\mathbf{i}) := W_\rho \setminus \bigcup_{\mathbf{j} \in S(\mathbf{i}, \rho^{\beta/2})} \mathbf{j} \tag{3.5}$$

for the complement with respect to W_ρ of the neighborhood of $\mathbf{i} \in V$.

Now, because in stationary and isotropic STIT tessellations there are a.s. no cells with pairs of parallel sides, we can restrict the considerations to the measurable set $\mathcal{T}' \subset \mathcal{T}$ of all tessellations which do not contain cells with pairs of parallel sides. This simplifies the study of incircles of the cells. For any $T \in \mathcal{T}'$, for any Borel subset $B \subset \mathbb{R}^2$, and for any threshold $v \geq 0$, let

$$M_B^{(T)} := \max_{z \in T : c(z) \in B} R(z) \quad \text{and} \quad N_B^{(T)}(v) := \sum_{z \in T : c(z) \in B} \mathbf{1}_{R(z) > v}.$$

Notice that $M_{(C(\mathbf{i}))^\circ}^{(T)}$ and $N_{(C(\mathbf{i}))^\circ}^{(T)}(v_\rho)$ are the maximum of inradii and the number of exceedances *outside* a neighborhood of $\mathbf{i}$. The following lemma provides the background to apply Lemma 3.4.

Lemma 3.5. *Let v_ρ be as in (1.5), with $t = 1$ and $\rho > \rho_0(\tau)$ (see (3.2)), and $\mathbf{i} \in V$ be fixed. Let $K = \left(\bigcup_{\mathbf{j} \in S(\mathbf{i}, \rho^{\beta/2})} \mathbf{j} \right) \ominus \mathbf{S}_0$ and $K' = \mathbf{i} \oplus \mathbf{S}_0$. Then*

(i) $\left\{ T \in \mathcal{T}' : v_\rho < M_{\mathbf{i}^\circ}^{(T)} \leq v_\rho^2 \right\} \in \mathcal{B}(\mathcal{T}_{K'}).$

(ii) $\left\{ T \in \mathcal{T}' : M_{(C(\mathbf{i}))^\circ}^{(T)} \leq v_\rho^2 \quad \text{and} \quad N_{(C(\mathbf{i}))^\circ}^{(T)}(v_\rho) = k \right\} \in \mathcal{B}(\mathcal{T}_{K^c})$ *for all $k \in \mathbb{N}_0$.*

4 Proofs of technical lemmas

Proof of Lemma 3.1 Let $B_1 = B(c_1, r)$ and $B_2 = B(c_2, r)$ be two disks with the same radius $r > 0$ and with centers $c_1, c_2 \in \mathbb{R}^2$. Denote by $[B_1 | B_2]$ the set of lines which separate B_1 and B_2, and write $\text{conv}(B_1 \cup B_2)$ for the convex hull of $B_1 \cup B_2$. According to Corollary 1 in [15], the probability $\mathbb{P}(\partial Y_1 \cap (B_1 \cup B_2) = \emptyset)$ can be written as follows:

9

- if $\Lambda([B_1]) + \Lambda([B_2]) \neq \Lambda([\mathrm{conv}(B_1 \cup B_2)])$, we have

$$\mathbb{P}\left(\partial Y_1 \cap (B_1 \cup B_2) = \emptyset\right) = e^{-\Lambda([\mathrm{conv}(B_1 \cup B_2)])}$$
$$+ \Lambda([B_1|B_2]) \cdot \frac{e^{-\Lambda([\mathrm{conv}(B_1 \cup B_2)])} - e^{-\Lambda([B_1])}e^{-\Lambda([B_2])}}{\Lambda([B_1]) + \Lambda([B_2]) - \Lambda([\mathrm{conv}(B_1 \cup B_2)])}, \quad (4.1)$$

- otherwise, we have

$$\mathbb{P}\left(\partial Y_1 \cap (B_1 \cup B_2) = \emptyset\right) = e^{-\Lambda([\mathrm{conv}(B_1 \cup B_2)])} + \Lambda([B_1|B_2])\, e^{-\Lambda([B_1])}e^{-\Lambda([B_2])}. \quad (4.2)$$

Now, let $d := \|c_2 - c_1\| \geq 2r$. It is clear that

$$\Lambda([B_1]) = \Lambda([B_2]) = 2r \quad \text{and} \quad \Lambda([\mathrm{conv}(B_1 \cup B_2)]) = 2r + 2d/\pi.$$

Moreover, because $[B_1|B_2] \subseteq [\overline{c_1 c_2}]$, we obtain $\Lambda([B_1|B_2]) \leq \Lambda([\overline{c_1 c_2}]) = \frac{2d}{\pi}$, where $\overline{c_1 c_2}$ denotes the linear segment connecting c_1 and c_2.

We discuss the two cases (4.1) and (4.2). First, assume that $d \neq \pi r$ and hence $\Lambda([B_1]) + \Lambda([B_2]) \neq \Lambda([\mathrm{conv}(B_1 \cup B_2)])$. Thus, according to (4.1), we have

$$\mathbb{P}\left(\partial Y_1 \cap (B_1 \cup B_2) = \emptyset\right) \leq e^{-(2r+2d/\pi)} + \frac{2d}{\pi} \cdot \frac{e^{-(2r+2d/\pi)} - e^{-4r}}{2r - 2d/\pi}.$$

Now, we provide an upper bound, which is independent of d, for the right-hand side. Taking $u := \frac{2d}{\pi} - 2r$, we have $u \geq (\frac{4}{\pi} - 2)r$ and

$$\mathbb{P}\left(\partial Y_1 \cap (B_1 \cup B_2) = \emptyset\right) \leq e^{-(u+4r)} + (u + 2r)\frac{e^{-(u+4r)} - e^{-4r}}{-u}$$
$$= e^{-4r}\left(e^{-u} + (u+2r) \cdot \frac{e^{-u} - 1}{-u}\right)$$
$$= e^{-4r}\left(1 + 2r \cdot \frac{1 - e^{-u}}{u}\right).$$

Notice that the function f defined as $f(u) = \frac{1-e^{-u}}{u}$ if $u \neq 0$, and $f(0) := 1$, is positive, continuous and strictly decreasing on $\mathbb{R}$. Since $u \geq (\frac{4}{\pi} - 2)r$, we have $\frac{1-e^{-u}}{u} \leq \frac{1-e^{-(\frac{4}{\pi}-2)r}}{(\frac{4}{\pi}-2)r}$. Hence,

$$\mathbb{P}\left(\partial Y_1 \cap (B_1 \cup B_2) = \emptyset\right) \leq e^{-4r}\left(1 + \frac{2}{2 - \frac{4}{\pi}}\left(e^{(2-\frac{4}{\pi})r} - 1\right)\right)$$
$$\leq \frac{2}{2 - \frac{4}{\pi}}\, e^{-2(1+\frac{2}{\pi})r}.$$

In the case $d = \pi r$, the equation (4.2) yields

$$\mathbb{P}\left(\partial Y_1 \cap (B_1 \cup B_2) = \emptyset\right) \leq e^{-(2r+2d/\pi)} + \frac{2d}{\pi}\, e^{-4r}$$
$$= (1 + 2r)\, e^{-4r}$$
$$= o(e^{-2(1+\frac{2}{\pi})r}),$$

which proves the assertion. □

Proof of Lemma 3.2 Let $H_1 \in \mathcal{H}$ be fixed, with normal direction $u_1 \in S^1$. According to (2.1), we have

$$G(H_1) = \int_{(S^1)^2} \int_{\mathbb{R}_+^2} \mathbf{1}_{c(H_1, H(r_2, u_2), H(r_3, u_3)) \in B(0, R)} \, \mathrm{d}r_{2:3} \, \sigma^{\otimes 2}(\mathrm{d}u_{2:3}).$$

Now, let $(u_2, u_3) \in (S^1)^2$ and $(r_2, r_3) \in (0, \infty)^2$ such that $H_{1:3} = (H_1, H_2, H_3)$ are in general position, with $H_2 = H(r_2, u_2)$ and $H_3 = H(r_3, u_3)$. For short, we write $c := c(H_{1:3})$. Let $< \cdot, \cdot >$ be the scalar product and identify the points c and u_i with their corresponding vectors. Furthermore, let $r(c, H)$ denote the distance of a line H to a point $c \in \mathbb{R}^2$. Elementary geometry yields $r(c, H_i) = r(0, H_i) - < u_i, c >$, $i = 1, 2, 3$. Hence, for $i = 2, 3$, we have

$$r_i = r(0, H_i) = r(0, H_1) - < u_1, c > + < u_i, c > . \tag{4.3}$$

Now, for each $u_2, u_3 \in S^1$, consider the change of variables $c \mapsto (r_2, r_3)$, where r_2, r_3 are two positive numbers such that $c(H_1, H(r_2, u_2), H(r_3, u_3)) = c$. According to (4.3), this map is linear and it is one-to-one. Its Jacobian does not depend on c, but only on u_i, $i = 1, 2, 3$, and is be bounded by a constant. This shows that $G(H_1)$ is lower than a constant multiplied by $\int_{(0, \infty)^2} \mathbf{1}_{c \in B(0, R)} \, \mathrm{d}c = \pi R^2$, which concludes the proof of Lemma 3.2. □

Proof of Lemma 3.3 This will be sketched only because it relies on the same idea as the proof of Lemma 3.2, see also the proof of Lemma A.1, (ii) of [4]. Let $H_1, H_2 \in \mathcal{H}$ be fixed. For each line H_3, the incenter $c(H_{1:3})$ belongs to one of the two bisecting lines associated with H_1 and H_2. By considering a linear change of variables whose Jacobian only depends on the normal vectors, we see that $G(H_1, H_2)$ is smaller than the diameter of $B(0, R)$ and thus $G(H_1, H_2) \le \eta R$ for some constant η. □

Proof of Lemma 3.4 First we write for $0 < s < t$

$$|\mathbb{P}(Y_t \in \mathcal{E}|Y_t \in \mathcal{A}) - \mathbb{P}(Y_t \in \mathcal{E})| \le |\mathbb{P}(Y_t \in \mathcal{E}|Y_t \in \mathcal{A}) - \mathbb{P}(Y_t \in \mathcal{E}, S(K, K') < s, Y_s \wedge K' = K'|Y_t \in \mathcal{A})|$$
$$+ |\mathbb{P}(Y_t \in \mathcal{E}, S(K, K') < s, Y_s \wedge K' = K'|Y_t \in \mathcal{A}) - \mathbb{P}(Y_t \in \mathcal{E})| .$$

According to Lemma 6.2 of [10], we can write the first term on the right-hand side as

$$\mathbb{P}(Y_t \in \mathcal{E}|Y_t \in \mathcal{A}) - \mathbb{P}(Y_t \in \mathcal{E}, S(K, K') < s, Y_s \wedge K' = K'|Y_t \in \mathcal{A})$$

$$= \mathbb{P}(Y_t \in \mathcal{E}|Y_t \in \mathcal{A}) - \mathbb{P}(Y_t \in \mathcal{E}, S(K, K') < s, Y_s \wedge K' = K') \cdot \frac{\mathbb{P}(Y_{t-s} \in \mathcal{A})}{\mathbb{P}(Y_t \in \mathcal{A})}.$$

For the second term, we apply Lemma 6.2 of [10] again and write

$$|\mathbb{P}(Y_t \in \mathcal{E}, S(K, K') < s, Y_s \wedge K' = K'|Y_t \in \mathcal{A}) - \mathbb{P}(Y_t \in \mathcal{E})|$$

$$\le \left| \mathbb{P}(Y_t \in \mathcal{E}, S(K, K') < s, Y_s \wedge K' = K') \cdot \frac{\mathbb{P}(Y_{t-s} \in \mathcal{A})}{\mathbb{P}(Y_t \in \mathcal{A})} - \mathbb{P}(Y_t \in \mathcal{E}) \cdot \frac{\mathbb{P}(Y_{t-s} \in \mathcal{A})}{\mathbb{P}(Y_t \in \mathcal{A})} \right|$$

$$+ \left| \mathbb{P}(Y_t \in \mathcal{E}) \cdot \frac{\mathbb{P}(Y_{t-s} \in \mathcal{A})}{\mathbb{P}(Y_t \in \mathcal{A})} - \mathbb{P}(Y_t \in \mathcal{E}) \right|$$

$$= \frac{\mathbb{P}(Y_{t-s} \in \mathcal{A})}{\mathbb{P}(Y_t \in \mathcal{A})} \mathbb{P}(\{Y_t \in \mathcal{E}\} \cap \{S(K, K') < s, Y_s \wedge K' = K'\}^c)$$

$$+ \left| \frac{\mathbb{P}(Y_{t-s} \in \mathcal{A})}{\mathbb{P}(Y_t \in \mathcal{A})} - 1 \right| \mathbb{P}(Y_t \in \mathcal{E}),$$

11

which concludes the proof of Lemma 3.4. $\qquad\square$

Proof of Lemma 3.5 First, we prove (i). To do it, for each $x \in \mathbb{R}^2$, $T \in \mathcal{T}'$, we denote by $d_T(x)$ the distance from the point x to the skeleton ∂T of the tessellation T. For a fixed T the function d_T is continuous, piecewise linear, and its local maxima are the incenters of the cells.

For all $x \in \mathbf{i}$, and all $r \leq v_\rho^2$, we have $B(x, r) \subset K'$, and therefore

$$\{d(x) > r\} := \{T \in \mathcal{T}' : d_T(x) > r\} = \{T \in \mathcal{T}' : B(x, r) \cap \partial T = \emptyset\} \in \mathcal{B}(\mathcal{T}_{K'}).$$

Let $\mathbb{Q}$ denote the set of rational numbers. The idea for the formal proof given below is the following. Choose an $n_0 \in \mathbb{N}_0$, large enough such that a *local* maximum $c(z)$ of d_T inside a cell z is focused on. Then this local maximum can be approximated by a sequence of points x_n, $n > n_0$, with rational coordinates. A point x_n can be chosen in a distance $\frac{1}{2n}$ from $c(z)$, not arbitrarily, but in a direction from $c(z)$ where the slope of the function d_T is smaller or equal than in the other directions. Notice that with this method the incenters which are located in the interior $\mathbf{i}^\circ$ of $\mathbf{i}$ can be identified only; for incenters on the boundary of $\mathbf{i}$ we would need information outside K'. In a stationary random tessellation there is almost surely no incenter on the boundary of $\mathbf{i}$.

For $\rho > \rho_0(\tau)$ and $T \in \mathcal{T}'$, we have the following logical equivalences:

$$v_\rho < M_{\mathbf{i}^\circ}^{(T)} \leq v_\rho^2$$
$$\iff \exists z \in T : c(z) \in \mathbf{i}^\circ, \, v_\rho < M_{\mathbf{i}^\circ}^{(T)} \leq v_\rho^2$$
$$\iff \exists n_0 \in \mathbb{N} \, \forall n \geq n_0 \, \exists x_n \in (\mathbf{i}^\circ \cap \mathbb{Q}^2) \, \forall x \in \left(B\left(x_n, \frac{1}{n_0}\right) \setminus B\left(x_n, \frac{1}{n}\right) \right) \cap \mathbb{Q}^2 :$$
$$d_T(x) < d_T(x_n) \text{ and } v_\rho < d_T(x_n) \leq v_\rho^2.$$

Thus, $\{T \in \mathcal{T}' : v_\rho < M_{\mathbf{i}^\circ}^{(T)} \leq v_\rho^2\}$ can be represented as a union, intersection or complement of countably many events of the type $\{d(x) > r\}$, with $x \in \mathbf{i}^\circ$ and $r \leq v_\rho^2$, and hence it is in $\mathcal{B}(\mathcal{T}_{K'})$. This concludes the proof of (i).

The proof of (ii) relies on the same idea as the proof of (i). Observe that for all $x \in (C(\mathbf{i}))^\circ$, and all $r \leq v_\rho^2$, we have that $B(x, r) \subset K^c$, and therefore $\{d(x) > r\} \in \mathcal{B}(\mathcal{T}_{K^c})$. Moreover, for any pair of points $x_1, x_2 \in (C(\mathbf{i}))^\circ$, the linear segment $\overline{x_1 x_2} \subset K^c$ and therefore $\{T \in \mathcal{T}' : \overline{x_1 x_2} \cap \partial T \neq \emptyset\} \in \mathcal{B}(\mathcal{T}_{K^c})$. The condition $\overline{x_{n,i} x_{n,j}} \cap \partial T \neq \emptyset$ ensures that $x_{n,i}$ and $x_{n,j}$ are located in different cells. For all $T \in \mathcal{T}'$ we have

$$M_{(C(\mathbf{i}))^\circ}^{(T)} \leq v_\rho^2 \iff \forall x \in (C(\mathbf{i}))^\circ \cap \mathbb{Q}^2 : B(x, v_\rho^2) \cap \partial T \neq \emptyset.$$

Furthermore, for all $T \in \mathcal{T}'$,

$$N_{(C(\mathbf{i}))^\circ}^{(T)} \geq k$$
$$\iff \exists n_0 \in \mathbb{N} \, \forall n \geq n_0 \, \exists (x_{n,1}, \ldots, x_{n,k}) \in \left((C(\mathbf{i}))^\circ \cap \mathbb{Q}^2 \right)^k :$$
$$(\forall 1 \leq i < j \leq k : \overline{x_{n,i} x_{n,j}} \cap \partial T \neq \emptyset) \text{ and}$$
$$\forall j \in \{1, \ldots, k\} \forall x \in \left(B\left(x_{n,j}, \frac{1}{n_0}\right) \setminus B\left(x_{n,j}, \frac{1}{n}\right) \right) \cap \mathbb{Q}^2 : d_T(x) < d_T(x_{n,j}) \text{ and } v_\rho < d_T(x_n).$$

Thus, the set $\left\{ T \in \mathcal{T}' : N_{(C(\mathbf{i}))^\circ}^{(T)} \geq k \quad \text{and} \quad M_{(C(\mathbf{i}))^\circ}^{(T)} \leq v_\rho^2 \right\}$ can be represented as a union, intersection or complement of countably many events of the type $\{d(x) > r\}$, with $x \in \mathbf{i}$ and $r \leq v_\rho^2$, and hence it is in $\mathcal{B}(\mathcal{T}_{K^c})$. $\qquad\square$

5 Proof of Theorem 1.1

Recall that it is sufficient to prove the theorem for the case $t = 1$ and that for $\rho > \rho_0(\tau)$ (see (3.2)) there can be at most one incircle with center in $\mathbf{i} \in V$ and radius larger than v_ρ, so that

$$N_{W_\rho}(v_\rho) = \sum_{\mathbf{i} \in V} \mathbf{1}_{M_\mathbf{i} > v_\rho}. \tag{5.1}$$

Now, according to (1.4) and (5.1), for all $\rho > \rho_0(\tau)$, we obtain that

$$\sum_{\mathbf{i} \in V} p_\mathbf{i} = \mathbb{E}\left[\sum_{\mathbf{i} \in V} \mathbf{1}_{M_\mathbf{i} > v_\rho}\right] = \mathbb{E}\left[N_{W_\rho}(v_\rho)\right] = \rho \; \mathbb{P}\left(R(\mathcal{Z}) > v_\rho\right) = \tau. \tag{5.2}$$

Thus, to prove Theorem 1.1, it suffices to show that $\sum_{\mathbf{i} \in V} \mathbf{1}_{M_\mathbf{i} > v_\rho}$ converges in total variation to a Poisson random variable Z with mean $\mathbb{E}[Z] = \tau$. According to Proposition 2.1, it is sufficient to prove that b_1, b_2 and b_3, defined in (3.4), converge to 0 as ρ goes to infinity. These proofs are given in Sections 5.1, 5.2 and 5.3, respectively.

5.1 Proof of the assertion that b_1 converges to 0 for $\rho \to \infty$

Because the STIT tessellation Y_1 is stationary, the value of $p_\mathbf{i}$ does not depend on $\mathbf{i}$. Therefore, for $\mathbf{i} \in V$, we have

$$b_1 \leq |V| \cdot \sup_{\mathbf{i} \in V} |S(\mathbf{i}, \rho^{\beta/2})| \cdot p_\mathbf{i}^2 \leq |V| \cdot \left(2\lfloor \rho^{\beta/2} \rfloor + 1\right)^2 \cdot p_\mathbf{i}^2.$$

Now, for $\rho > \rho_0(\tau)$, we observe that

$$p_\mathbf{i} = \mathbb{P}\left(M_\mathbf{i} > v_\rho\right) = \mathbb{E}\left[\sum_{z \in Y_1 : c(z) \in \mathbf{i}} \mathbf{1}_{R(z) > v_\rho}\right] = a(\mathbf{i}) \, \gamma_1 \; \mathbb{P}\left(R(\mathcal{Z}) > v_\rho\right) = a(\mathbf{i}) \, \gamma_1 e^{-2v_\rho}, \tag{5.3}$$

where the last two equalities come from (1.1) and (1.2). Since the area of $\mathbf{i}$ is $a(\mathbf{i}) = \frac{\pi\rho}{|V|}$, it follows from (1.5) that

$$b_1 \leq \frac{\tau^2}{|V|} \left(2\rho^{\beta/2} + 1\right)^2.$$

According to (3.1), this implies that $b_1 = O\left(\rho^{-(1-\beta)} \log\log\rho\right)$. Since $\beta < 1$, this proves that b_1 converges to 0 as ρ goes to infinity.

5.2 Proof of the assertion that b_2 converges to 0 for $\rho \to \infty$

Let $\mathbf{i}, \mathbf{j} \in V$ be fixed, with $\mathbf{i} \neq \mathbf{j}$. In the same spirit as in (5.1), for $\rho > \rho_0(\tau)$, there are at most two incircles with radii larger than v_ρ and centers in $\mathbf{i}$ and $\mathbf{j}$ respectively. Therefore

$$p_{\mathbf{i}\mathbf{j}} = \mathbb{P}\left(M_\mathbf{i} > v_\rho, M_\mathbf{j} > v_\rho\right) = \mathbb{E}\left[\sum_{(z_1, z_2) \in Y_1^2 : (c(z_1), c(z_2)) \in \mathbf{i} \times \mathbf{j}} \mathbf{1}_{R(z_1) > v_\rho} \mathbf{1}_{R(z_2) > v_\rho}\right]. \tag{5.4}$$

13

To deal with the right-hand side, we consider three cases, regarding the number of tangential (to the incircle) maximal segments that are common to both cells. By a common tangential maximal segment (CTS) of the cells z_1 and z_2 we mean a maximal segment $s \in m_1$ which is tangential to the incircles of z_1 and z_2 simultaneously, i.e. $s \cap B(z_1) \neq \emptyset$ and $s \cap B(z_2) \neq \emptyset$. Notice that the cells z_1 and z_2 can have a common segment which is not a CTS. Thus we write $p_{\mathbf{ij}}$ as

$$p_{\mathbf{ij}} = p_{\mathbf{ij}}(0) + p_{\mathbf{ij}}(1) + p_{\mathbf{ij}}(2),$$

where for $0 \le k \le 2$,

$$p_{\mathbf{ij}}(k) := \mathbb{E}\left[\sum_{(z_1,z_2)\in Y_1^2:(c(z_1),c(z_2))\in\mathbf{i}\times\mathbf{j}} \mathbf{1}_{R(z_1)>v_\rho} \mathbf{1}_{R(z_2)>v_\rho} \mathbf{1}_{(z_1,\,z_2\text{ have }k\text{ CTS})} \right]$$

We prove below that $p_{\mathbf{ij}}(k) = O\left((\log\log\rho)^2 \cdot \log\rho \cdot \rho^{-2(1+\epsilon)}\right)$ for each $k = 0,1,2$ and $0 < \epsilon \le \frac{2}{\pi}$. We begin with the case $k = 0$. To do it, we will use two formulas of Stochastic Geometry and Integral Geometry respectively, namely a Mecke-type formula for STIT tessellations and a Blaschke-Petkantschin type change of variables. The cases $k = 1$ and $k = 2$ will be dealt in a similar way, but also applying Lemmas 3.2 and 3.3, respectively.

5.2.1 Case $k = 0$

We rewrite $p_{\mathbf{ij}}(0)$ in terms of maximal segments (instead of cells) of Y_1. This yields

$$p_{\mathbf{ij}}(0) = \frac{1}{3!\cdot 3!}\mathbb{E}\left[\sum_{s_{1:3}\in m_1^3} \sum_{q_{1:3}\in m_1^3\setminus\{s_{1:3}\}} \mathbf{1}_{R(s_{1:3})>v_\rho,R(q_{1:3})>v_\rho} \mathbf{1}_{\partial Y_1 \cap (B^o(s_{1:3})\cup B^o(q_{1:3}))=\emptyset} \mathbf{1}_{(c(s_{1:3}),c(q_{1:3}))\in\mathbf{i}\times\mathbf{j}} \right]$$

where the segments $s_{1:3}$ are pairwise different, and so are the $q_{1:3}$ too. Thanks to the Mecke-type formula for STIT tessellations, Theorem 3.1 of [14], there is an $\eta_M > 0$, such that

$$p_{\mathbf{ij}}(0) \le \frac{2\eta_M}{3!\cdot 3!}\int_{\mathcal{H}^6} \mathbb{P}\left(\partial Y_1 \cap (B^o(H_{1:3})\cup B^o(H'_{1:3})) = \emptyset \right) \mathbf{1}_{(c(H_{1:3}),c(H'_{1:3}))\in\mathbf{i}\times\mathbf{j}} \mathbf{1}_{R(H_{1:3})>R(H'_{1:3})>v_\rho}\, \mathrm{d}H_{1:3}\mathrm{d}H'_{1:3}.$$

Here, the inequality is due to the omission of the indicators of the events $\{H_1, H_2, H_3\} \cap B(q_{1:3}) = \emptyset$ and $\{H'_1, H'_2, H'_3\} \cap B(s_{1:3}) = \emptyset$. The factor 2 appears because we have added the indicator function $\mathbf{1}_{R(H_{1:3})>R(H'_{1:3})}$, which for a stationary and isotropic tessellation means no loss of generality. The factor η_M comes from the application of the Mecke-type formula for the different possible arrangements of $s_{1:3} \in m_1^3$ and $q_{1:3} \in m_1^3$. We remark that the Mecke-type formula for maximal segments of a STIT tessellation is technically much more involved than the respective Mecke formula for a Poisson line tessellation. Here we omit a detailed derivation of the formula above, as it would require quite a few pages; cf. the proofs in [14].

Now, let $\epsilon > 0$ be fixed. For $H_{1:3}$ and $H'_{1:3}$ with $R(H_{1:3}) > R(H'_{1:3})$ we write $B(c_1, r_1) := B(H_{1:3})$ and $B(c_2, r_2) := B(H'_{1:3})$. We consider two sub-cases. First, if $r_1 \ge v_\rho(1 + \epsilon)$, we use the fact that

$$\mathbb{P}\left(\partial Y_1 \cap (B(c_1, r_1)\cup B(c_2, r_2)) = \emptyset \right) \le \mathbb{P}\left(\partial Y_1 \cap B(c_1, r_1) = \emptyset \right).$$

This yields

$$\mathbb{P}\left(\partial Y_1 \cap (B(c_1, r_1)\cup B(c_2, r_2)) = \emptyset \right) \le e^{-2r_1}.$$

14

Second, if $r_1 < v_\rho(1 + \epsilon)$, we use the inequality

$$\mathbb{P}\left(\partial Y_1 \cap (B(c_1, r_1) \cup B(c_2, r_2)) = \emptyset\right) \leq \mathbb{P}\left(\partial Y_1 \cap (B(c_1, r_2) \cup B(c_2, r_2)) = \emptyset\right),$$

which follows from the assumption that $r_1 > r_2$. Hence, according to Lemma 3.1, there exists a constant $\eta_1 > 0$ such that

$$\mathbb{P}\left(\partial Y_1 \cap (B(c_1, r_1) \cup B(c_2, r_2)) = \emptyset\right) \leq \eta_1\, e^{-2(1 + \frac{2}{\pi})r_2}.$$

Summarizing, there exists a constant $\eta > 0$ for which

$$p_{\mathbf{ij}}(0) \leq \eta\, (p_{\mathbf{ij}}^{>\epsilon}(0) + p_{\mathbf{ij}}^{<\epsilon}(0)),$$

where

$$p_{\mathbf{ij}}^{>\epsilon}(0) := \int_{\mathcal{H}^6} e^{-2R(H_{1:3})} \mathbf{1}_{(c(H_{1:3}),c(H'_{1:3}))\in\mathbf{i}\times\mathbf{j}}\, \mathbf{1}_{R(H_{1:3})>R(H'_{1:3})>v_\rho}\, \mathbf{1}_{R(H_{1:3})\geq v_\rho(1+\epsilon)}\, \mathrm{d}H_{1:3}\mathrm{d}H'_{1:3},$$

and

$$p_{\mathbf{ij}}^{<\epsilon}(0) := \int_{\mathcal{H}^6} e^{-2(1+\frac{2}{\pi})R(H'_{1:3})} \mathbf{1}_{(c(H_{1:3}),c(H'_{1:3}))\in\mathbf{i}\times\mathbf{j}}\, \mathbf{1}_{v_\rho(1+\epsilon)>R(H_{1:3})>R(H'_{1:3})>v_\rho}\, \mathrm{d}H_{1:3}\mathrm{d}H'_{1:3}.$$

Now we provide upper bounds for $p_{\mathbf{ij}}^{>\epsilon}(0)$ and $p_{\mathbf{ij}}^{<\epsilon}(0)$.

(i) Upper bound for $p_{\mathbf{ij}}^{>\epsilon}(0)$ We apply a Blaschke-Petkantschin type change of variables (see e.g. Theorem 7.3.2 of [18]). To do it we denote by $a(u_{1:3})$ the area of the convex hull of $u_{1:3} \in (S^1)^3$. This gives

$$p_{\mathbf{ij}}^{>\epsilon}(0) = \int_{(S^1)^6} \int_{\mathbf{i}\times\mathbf{j}} \int_{\mathbb{R}_+^2} a(u_{1:3})\, a(u'_{1:3})\, e^{-2r_1} \mathbf{1}_{r_1>r_2>v_\rho}\, \mathbf{1}_{r_1\geq v_\rho(1+\epsilon)}\, \mathrm{d}r_1\mathrm{d}r_2\mathrm{d}c_1\mathrm{d}c_2 \sigma^{\otimes 3}(\mathrm{d}u_{1:3})\sigma^{\otimes 3}(\mathrm{d}u'_{1:3})$$

$$\leq \eta_2\, a(\mathbf{i})^2\, v_\rho\, e^{-2v_\rho(1+\epsilon)},$$

for some positive constant η_2. This, together with (1.5), and the fact that $a(\mathbf{i}) = O(\log\log\rho)$, implies

$$p_{\mathbf{ij}}^{>\epsilon}(0) = O\left((\log\log\rho)^2 \cdot \log\rho \cdot \rho^{-2(1+\epsilon)}\right).$$

(ii) Upper bound for $p_{\mathbf{ij}}^{<\epsilon}(0)$ Again we apply a Blaschke-Petkantschin type change of variables. This yields

$$p_{\mathbf{ij}}^{<\epsilon}(0) = \int_{(S^1)^6} \int_{\mathbf{i}\times\mathbf{j}} \int_{\mathbb{R}_+^2} a(u_{1:3})\, a(u'_{1:3})\, e^{-2(1+\frac{2}{\pi})r_2} \mathbf{1}_{v_\rho(1+\epsilon)>r_1>r_2>v_\rho}\, \mathrm{d}r_1\mathrm{d}r_2\mathrm{d}c_1\mathrm{d}c_2 \sigma^{\otimes 3}(\mathrm{d}u_{1:3})\sigma^{\otimes 3}(\mathrm{d}u'_{1:3})$$

$$\leq \eta_3\, a(\mathbf{i})^2\, v_\rho\, e^{-2(1+\frac{2}{\pi})v_\rho},$$

for some positive constant η_3. In the same spirit as above, we get

$$p_{\mathbf{ij}}^{<\epsilon}(0) = O\left((\log\log\rho)^2 \cdot \log\rho \cdot \rho^{-2(1+\frac{2}{\pi})}\right).$$

Combining the upper bounds for $p_{\mathbf{ij}}^{>\epsilon}(0)$ and for $p_{\mathbf{ij}}^{<\epsilon}(0)$ we obtain for $0 < \epsilon \leq \frac{2}{\pi}$ that

$$p_{\mathbf{ij}}(0) = O\left((\log\log\rho)^2 \cdot \log\rho \cdot \rho^{-2(1+\epsilon)}\right).$$

5.2.2 Case $k = 1$

Now the calculation of an upper bound for $p_{\mathbf{ij}}(1)$ will be sketched only, because we proceed in the same spirit as in the case $k = 0$.

$$p_{\mathbf{ij}}(1) :=$$

$$\frac{1}{3! \cdot 2!} \mathbb{E}\left[\sum_{s_{1:3} \in m_1^3} \sum_{q_{2:3} \in m_1^3 \setminus \{s_{1:3}\}} \mathbf{1}_{R(s_{1:3}) > v_\rho, R(s_1, q_{2:3}) > v_\rho} \mathbf{1}_{\partial Y_1 \cap (B^o(s_{1:3}) \cup B^o(s_1, q_{2:3})) = \emptyset} \mathbf{1}_{(c(s_{1:3}), c(s_1, q_{2:3})) \in \mathbf{i} \times \mathbf{j}} \right].$$

Applying the Mecke-type formula for STIT tessellations, and discussing two sub-cases as above, namely $r_1 \geq v_\rho(1 + \epsilon)$ and $r_1 < v_\rho(1 + \epsilon)$, we see that that there is an $\eta > 0$ such that

$$p_{\mathbf{ij}}(1) \leq \eta \left(p_{\mathbf{ij}}^{> \epsilon}(1) + p_{\mathbf{ij}}^{< \epsilon}(1) \right),$$

where

$$p_{\mathbf{ij}}^{> \epsilon}(1) := \int_{\mathcal{H}^5} e^{-2R(H_{1:3})} \mathbf{1}_{(c(H_{1:3}), c(H_1, H_{2:3}')) \in \mathbf{i} \times \mathbf{j}} \mathbf{1}_{v_\rho < R(H_1, H_{2:3}') < R(H_{1:3})} \mathbf{1}_{R(H_{1:3}) \geq v_\rho(1 + \epsilon)} \, \mathrm{d}H_{1:3} \mathrm{d}H_{2:3}',$$

and

$$p_{\mathbf{ij}}^{< \epsilon}(1) := \int_{\mathcal{H}^5} e^{-2(1 + \frac{2}{\pi})R(H_1, H_{2:3}')} \mathbf{1}_{(c(H_{1:3}), c(H_1, H_{2:3}')) \in \mathbf{i} \times \mathbf{j}} \mathbf{1}_{v_\rho < R(H_1, H_{2:3}') < R(H_{1:3}) < v_\rho(1 + \epsilon)} \, \mathrm{d}H_{1:3} \mathrm{d}H_{2:3}'.$$

Below, we provide upper bounds for $p_{\mathbf{ij}}^{> \epsilon}(1)$ and $p_{\mathbf{ij}}^{< \epsilon}(1)$.

(i) Upper bound for $p_{\mathbf{ij}}^{> \epsilon}(1)$ Because $\mathbf{1}_{R(H_1, H_{2:3}') > v_\rho} \leq 1$, it follows from Fubini's theorem that

$$p_{\mathbf{ij}}^{> \epsilon}(1) \leq \int_{\mathcal{H}^3} e^{-2R(H_{1:3})} \mathbf{1}_{c(H_{1:3}) \in \mathbf{i}} \mathbf{1}_{R(H_{1:3}) \geq v_\rho(1 + \epsilon)} \left(\int_{\mathcal{H}^2} \mathbf{1}_{c(H_1, H_{2:3}') \in \mathbf{j}} \mathbf{1}_{R(H_1, H_{2:3}') < R(H_{1:3})} \, \mathrm{d}H_{2:3}' \right) \mathrm{d}H_{1:3}.$$

Since $\mathbf{j}$ is a square with diameter $\sqrt{2}\frac{\sqrt{\pi \rho}}{\left[\sqrt{\frac{\pi \rho}{\log \log \rho}} \right]}$, it follows from Lemma 3.2 that for all lines H_1, there is a constant $\eta_4 > 0$ such that

$$\int_{\mathcal{H}^2} \mathbf{1}_{c(H_1, H_{2:3}') \in \mathbf{j}} \mathbf{1}_{R(H_1, H_{2:3}') < R(H_{1:3})} \, \mathrm{d}H_{2:3}' \leq \eta_4 \, \log \log \rho.$$

Thus

$$p_{\mathbf{ij}}^{> \epsilon}(1) \leq \eta_4 \, \log \log \rho \int_{\mathcal{H}^3} e^{-2R(H_{1:3})} \mathbf{1}_{c(H_{1:3}) \in \mathbf{i}} \mathbf{1}_{R(H_{1:3}) \geq v_\rho(1 + \epsilon)} \, \mathrm{d}H_{1:3}$$

$$= \eta_5 \, a(\mathbf{i}) \, \log \log \rho \int_{v_\rho(1 + \epsilon)}^{\infty} e^{-2r} \mathrm{d}r$$

$$= O\left((\log \log \rho)^2 \cdot \rho^{-2(1 + \epsilon)} \right),$$

where the second line comes from the Blaschke-Petkantschin type change of variables, and $\eta_5 > 0$.

16

(ii) Upper bound for $p_{\mathbf{ij}}^{<\epsilon}(1)$ This time we write

$$p_{\mathbf{ij}}^{<\epsilon}(1) \leq \int_{\mathcal{H}^3} e^{-2(1+\frac{2}{\pi})R(H_1,H_{2:3}')} \mathbf{1}_{c(H_1,H_{2:3}')\in\mathbf{j}} \, \mathbf{1}_{v_\rho<R(H_1,H_{2:3}')}$$

$$\times \left(\int_{\mathcal{H}^2} \mathbf{1}_{c(H_{1:3})\in\mathbf{i}} \mathbf{1}_{R(H_{1:3})<v_\rho(1+\epsilon)} \, \mathrm{d}H_{2:3} \right) \mathrm{d}H_1 \mathrm{d}H_{2:3}'.$$

According to Lemma 3.2, we have for some constant $\eta_6 > 0$

$$\int_{\mathcal{H}^2} \mathbf{1}_{c(H_{1:3})\in\mathbf{i}} \mathbf{1}_{R(H_{1:3})<v_\rho(1+\epsilon)} \, \mathrm{d}H_{2:3} \leq \eta_6 \, \log\log\rho.$$

Thus, for some constant $\eta_7 > 0$

$$p_{\mathbf{ij}}^{<\epsilon}(1) \leq \eta_6 \, \log\log\rho \int_{\mathcal{H}^3} e^{-2(1+\frac{2}{\pi})R(H_1,H_{2:3}')} \mathbf{1}_{c(H_1,H_{2:3}')\in\mathbf{j}} \mathbf{1}_{v_\rho<R(H_1,H_{2:3}')} \, \mathrm{d}H_1 \mathrm{d}H_{2:3}'$$

$$= \eta_7 \, a(\mathbf{j}) \, \log\log\rho \int_{v_\rho}^{\infty} e^{-2(1+\frac{2}{\pi})r} dr$$

$$= O\left((\log\log\rho)^2 \cdot \rho^{-2(1+\frac{2}{\pi})} \right),$$

where the second line again comes from the Blaschke-Petkantschin type change of variables. Summarizing, we obtain that $p_{\mathbf{ij}}(1) = O\left((\log\log\rho)^2 \cdot \rho^{-2(1+\epsilon)} \right)$ for $0 < \epsilon \leq \frac{2}{\pi}$.

5.2.3   Case $k = 2$

Proceeding now exactly along the same lines as above, we see that there is an $\eta > 0$ such that

$$p_{\mathbf{ij}}(2) \leq \eta \left(p_{\mathbf{ij}}^{>\epsilon}(2) + p_{\mathbf{ij}}^{<\epsilon}(2) \right),$$

where

$$p_{\mathbf{ij}}^{>\epsilon}(2) := \int_{\mathcal{H}^4} e^{-2R(H_{1:3})} \mathbf{1}_{(c(H_{1:3}),c(H_{1:2},H_3'))\in\mathbf{i}\times\mathbf{j}} \mathbf{1}_{R(H_{1:3})>R(H_{1:2},H_3')>v_\rho} \mathbf{1}_{R(H_{1:3})\geq v_\rho(1+\epsilon)} \, \mathrm{d}H_{1:3} \mathrm{d}H_3',$$

and

$$p_{\mathbf{ij}}^{<\epsilon}(2) := \int_{\mathcal{H}^4} e^{-2(1+\frac{2}{\pi})R(H_{1:2},H_3')} \mathbf{1}_{(c(H_{1:3}),c(H_{1:2},H_3'))\in\mathbf{i}\times\mathbf{j}} \mathbf{1}_{v_\rho(1+\epsilon)>R(H_{1:3})>R(H_{1:2},H_3')>v_\rho} \, \mathrm{d}H_{1:3} \mathrm{d}H_3'.$$

(i) Upper bound for $p_{\mathbf{ij}}^{>\epsilon}(2)$ We write

$$p_{\mathbf{ij}}^{>\epsilon}(2) \leq \int_{\mathcal{H}^3} e^{-2R(H_{1:3})} \mathbf{1}_{c(H_{1:3})\in\mathbf{i}} \mathbf{1}_{R(H_{1:3})\geq v_\rho(1+\epsilon)} \left(\int_{\mathcal{H}} \mathbf{1}_{c(H_{1:2},H_3')\in\mathbf{j}} \mathbf{1}_{R(H_{1:2},H_3')<R(H_{1:3})} \, \mathrm{d}H_3' \right) \mathrm{d}H_{1:3}.$$

Since $\mathbf{j}$ is a square with diameter $\sqrt{2}\frac{\sqrt{\pi}\,\rho}{\left\lfloor\sqrt{\frac{\pi\,\rho}{\log\log\rho}}\right\rfloor}$, it follows from Lemma 3.3 that for all $H_{1:3}$, there is a constant $\eta_8 > 0$ such that

$$\int_{\mathcal{H}} \mathbf{1}_{c(H_{1:2},H_3')\in\mathbf{j}} \mathbf{1}_{R(H_{1:2},H_3')<R(H_{1:3})} \, \mathrm{d}H_3' \leq \eta_8 \sqrt{\log\log\rho}.$$

Proceeding along the same lines as above, we obtain

$$p_{\mathbf{ij}}^{>\epsilon}(2) = O\left((\log\log\rho)^{\frac{3}{2}} \cdot \rho^{-2(1+\epsilon)} \right).$$

17

(ii) Upper bound for $p_{\mathbf{ij}}^{<\epsilon}(2)$ Now

$$p_{\mathbf{ij}}^{<\epsilon}(2) \le \int_{\mathcal{H}^3} e^{-2(1+\frac{2}{\pi})R(H_{1:2}, H_3')} \mathbf{1}_{c(H_{1:2}, H_3') \in \mathbf{j}} \, \mathbf{1}_{v_\rho < R(H_{1:2}, H_3')} \left(\int_{\mathcal{H}} \mathbf{1}_{c(H_{1:3}) \in \mathbf{i}} \, \mathbf{1}_{R(H_{1:3}) < v_\rho(1+\epsilon)} \, \mathrm{d}H_3 \right) \mathrm{d}H_{1:2} \mathrm{d}H_3'.$$

This yields

$$p_{\mathbf{ij}}^{<\epsilon}(2) = O\left((\log\log\rho)^{\frac{3}{2}} \cdot \rho^{-2(1+\frac{2}{\pi})} \right).$$

Summarizing, we obtain $p_{\mathbf{ij}}(2) = O\left((\log\log\rho)^{\frac{3}{2}} \cdot \rho^{-2(1+\epsilon)} \right)$ for $0 < \epsilon \le \frac{2}{\pi}$.

Now, having upper bounds for $p_{\mathbf{ij}}(k)$, $k = 0, 1, 2$, we can complete the proof that b_2 converges to 0 as $\rho \to \infty$. Indeed, let $\epsilon \in (0, \frac{2}{\pi}]$ and $\beta \in (0, 1)$ be fixed. Let $\epsilon' := 2(1 + \epsilon) - (1 + \beta)$. Then

$$b_2 = \sum_{\mathbf{i} \in V} \sum_{\mathbf{i} \ne \mathbf{j} \in S(\mathbf{i}, \rho^{\beta/2})} p_{\mathbf{ij}} \le |V| \cdot |S(\mathbf{i}, \rho^{\beta/2})| \cdot \sum_{k=0}^{2} p_{\mathbf{ij}}(k) = O\left(\log\log\rho \cdot \log\rho \cdot \rho^{-\epsilon'} \right).$$

Since $\epsilon' > 0$, this proves that b_2 converges to 0 as ρ goes to infinity.

5.3   Proof of the assertion that b_3 converges to 0 for $\rho \to \infty$

First, we rewrite b_3 as a series. To do it, let $\rho > \rho_0(\tau)$ and let $\mathbf{i} \in V$. According to (3.2), we know that $\sum_{\mathbf{j} \notin S(\mathbf{i}, \rho^{\beta/2})} \mathbf{1}_{M_{\mathbf{j}} > v_\rho} = N_{C(\mathbf{i})}(v_\rho)$, where $C(\mathbf{i})$ is defined in (3.5). Now, using the Bayes theorem, elementary calculations on conditional probabilities yield

$$b_3 = \sum_{\mathbf{i} \in V} p_{\mathbf{i}} \sum_{k=0}^{\infty} \left| \mathbb{P}\left(N_{C(\mathbf{i})}(v_\rho) = k | M_{\mathbf{i}} > v_\rho \right) - \mathbb{P}\left(N_{C(\mathbf{i})}(v_\rho) = k \right) \right|$$

$$\le \left(\sum_{\mathbf{i} \in V} p_{\mathbf{i}} \right) \cdot \left(\sup_{\mathbf{i} \in V} \sum_{k=0}^{\infty} \left| \mathbb{P}\left(N_{C(\mathbf{i})}(v_\rho) = k | M_{\mathbf{i}} > v_\rho \right) - \mathbb{P}\left(N_{C(\mathbf{i})}(v_\rho) = k \right) \right| \right).$$

Moreover, according to (1.4) and (5.3), we have $\sum_{\mathbf{i} \in V} p_{\mathbf{i}} = \tau$. Thus, to prove that b_3 converges to 0, it is sufficient to prove that b_3' converges to 0, where

$$b_3' := \sup_{\mathbf{i} \in V} \sum_{k=0}^{\infty} \left| \mathbb{P}\left(N_{C(\mathbf{i})}(v_\rho) = k | M_{\mathbf{i}} > v_\rho \right) - \mathbb{P}\left(N_{C(\mathbf{i})}(v_\rho) = k \right) \right|.$$

The main idea is to apply Lemmas 3.4 and 3.5. To be in the framework of these lemmas, we intersect the events appearing in the series with the events $\{M_{C(\mathbf{i})} \le v_\rho^2\}$ and $\{M_{\mathbf{i}} \le v_\rho^2\}$ respectively. Notice that these two events occur with high probability. With standard computations, we can prove that for each 4-tuple of events A, B, C, D, with $\mathbb{P}(B \cap D) \ne 0$, we have

$$|\mathbb{P}(A|B) - \mathbb{P}(A)| \le |\mathbb{P}(A \cap C|B \cap D) - \mathbb{P}(A \cap C)| + \frac{1}{\mathbb{P}(B)}(2\mathbb{P}(A \cap C^c) + \mathbb{P}(A \cap D^c) + 2\mathbb{P}(A)\mathbb{P}(D^c)).$$

Applying the above inequality to the events $A = \{N_{C(\mathbf{i})}(v_\rho) = k\}$, $B = \{M_{\mathbf{i}} > v_\rho\}$, $C = \{M_{C(\mathbf{i})} \le v_\rho^2\}$ and $D = \{M_{\mathbf{i}} \le v_\rho^2\}$, we obtain for all $\mathbf{i}$ and all $k \in \mathbb{N}_0$:

$$\left| \mathbb{P}\left(N_{C(\mathbf{i})}(v_\rho) = k | M_{\mathbf{i}} > v_\rho \right) - \mathbb{P}\left(N_{C(\mathbf{i})}(v_\rho) = k \right) \right| \le p_{k,\mathbf{i}} + q_{k,\mathbf{i}},$$

where

$$p_{k,\mathbf{i}} = \left| \mathbb{P}\left(\{N_{C(\mathbf{i})}(v_\rho) = k\} \cap \{M_{C(\mathbf{i})} \le v_\rho^2\} \,\middle|\, v_\rho < M_{\mathbf{i}} \le v_\rho^2 \right) - \mathbb{P}\left(\{N_{C(\mathbf{i})}(v_\rho) = k\} \cap \{M_{C(\mathbf{i})} \le v_\rho^2\} \right) \right|,$$

and

$$q_{k,\mathbf{i}} = \frac{1}{\mathbb{P}\left(M_{\mathbf{i}} > v_\rho\right)} \Big(2\,\mathbb{P}\left(\{N_{C(\mathbf{i})}(v_\rho) = k\} \cap \{M_{C(\mathbf{i})} > v_\rho^2\} \right) + \mathbb{P}\left(\{N_{C(\mathbf{i})}(v_\rho) = k\} \cap \{M_{\mathbf{i}} > v_\rho^2\} \right)$$
$$+ 2\,\mathbb{P}\left(N_{C(\mathbf{i})}(v_\rho) = k \right) \mathbb{P}\left(M_{\mathbf{i}} > v_\rho^2 \right) \Big).$$

Thus, to prove that b_3' converges to 0, we have to prove that $\sup_{\mathbf{i} \in V} \sum_{k=0}^\infty p_{k,\mathbf{i}}$ and $\sup_{\mathbf{i} \in V} \sum_{k=0}^\infty q_{k,\mathbf{i}}$ converge to 0. This is done in Subsections 5.3.2 and 5.3.1. We begin with $\sup_{\mathbf{i} \in V} \sum_{k=0}^\infty q_{k,\mathbf{i}}$ because it is the simplest case.

5.3.1 Proof of the assertion that $\sup_{\mathbf{i} \in V} \sum_{k=0}^\infty q_{k,\mathbf{i}}$ converges to 0

Roughly, the fact that $\sup_{\mathbf{i} \in V} \sum_{k=0}^\infty q_{k,\mathbf{i}}$ converges to 0 comes from the fact that the events $\{M_{C(\mathbf{i})} \le v_\rho^2\}$ and $\{M_{\mathbf{i}} \le v_\rho^2\}$ occur with high probability. Let $\mathbf{i} \in V$. Summing over $k \in \mathbb{N}_0$, we have

$$\sum_{k=0}^\infty q_{k,\mathbf{i}} = \frac{1}{\mathbb{P}\left(M_{\mathbf{i}} > v_\rho\right)} \left(2\,\mathbb{P}\left(M_{C(\mathbf{i})} > v_\rho^2 \right) + 3\,\mathbb{P}\left(M_{\mathbf{i}} > v_\rho^2 \right) \right).$$

Now, analogously to (5.3), we know that

$$\mathbb{P}\left(M_{C(\mathbf{i})} > v_\rho^2 \right) \le \mathbb{E}\left[\sum_{\mathbf{j} \in C(\mathbf{i})} \mathbf{1}_{M_{\mathbf{j}} > v_\rho^2} \right] = \gamma_1 a(C(\mathbf{i}))\ \mathbb{P}\left(R(\mathcal{Z}) > v_\rho^2 \right).$$

Furthermore, the stationarity of the tessellation yields that $\mathbb{P}\left(M_{\mathbf{i}} > v_\rho^2 \right) \le \mathbb{P}\left(M_{C(\mathbf{i})} > v_\rho^2 \right)$ for all ρ for which $a(\mathbf{i}) \le a(C(\mathbf{i}))$. Thus

$$\sum_{k=0}^\infty q_{k,\mathbf{i}} \le \frac{5\,\mathbb{P}\left(M_{C(\mathbf{i})} > v_\rho^2 \right)}{\mathbb{P}\left(M_{\mathbf{i}} > v_\rho \right)} \le \frac{5a(C(\mathbf{i}))\,\mathbb{P}\left(R(\mathcal{Z}) > v_\rho^2 \right)}{a(\mathbf{i})\,\mathbb{P}\left(R(\mathcal{Z}) > v_\rho \right)}.$$

Since $a(C(\mathbf{i})) \le a(W_\rho)$ and $a(\mathbf{i}) = \frac{a(W_\rho)}{|V|}$, we obtain from (3.1) that

$$\sum_{k=0}^\infty q_{k,\mathbf{i}} \le \frac{5\pi\rho}{\log\log\rho}\ \frac{\mathbb{P}\left(R(\mathcal{Z}) > v_\rho^2 \right)}{\mathbb{P}\left(R(\mathcal{Z}) > v_\rho \right)}.$$

An application of (1.2) and (1.5) yields

$$\sum_{k=0}^\infty q_{k,\mathbf{i}} = O\left((\log\log\rho)^{-1}\, \rho^{-\frac{1}{2}\log\rho + \log\tau + 2} \right).$$

As the last term does not depend on $\mathbf{i} \in V$, this is also an upper bound for $\sup_{\mathbf{i} \in V} \sum_{k=0}^\infty q_{k,\mathbf{i}}$. Obviously it converges to 0 as $\rho \to \infty$.

19

5.3.2 Proof of the assertion that $\sup_{\mathbf{i} \in V} \sum_{k=0}^{\infty} p_{k,\mathbf{i}}$ converges to 0

Let $\mathbf{i} \in V$ be fixed. For each $0 < s < 1$, we denote by $M_{\mathbf{i}}^{[1-s]}$ the maximum of the inradii over all cells with nucleus in $\mathbf{i}$ for a STIT tessellation at time $1 - s$. When the time is not specified, the underlying STIT tessellation is at time 1, e.g. $M_{\mathbf{i}}$ denotes the same maximum but this time for a STIT tessellation at time 1, in accordance with (2.2). Now taking

$$
K = \left(\bigcup_{\mathbf{j} \in S(\mathbf{i}, \rho^{\beta/2})} \mathbf{j} \right) \ominus \mathbf{S}_0 \quad \text{and} \quad K' = \mathbf{i} \oplus \mathbf{S}_0,
$$

it follows from Lemmas 3.4 and 3.5 that for each $s \in (0, 1)$,

$$
\begin{aligned}
p_{k,\mathbf{i}} \leq\ & \mathbb{P}\left(\{N_{C(\mathbf{i})}(v_\rho) = k\} \cap \{M_{C(\mathbf{i})} \leq v_\rho^2\} | v_\rho < M_{\mathbf{i}} \leq v_\rho^2 \right) \\
& - \frac{\mathbb{P}\left(v_\rho < M_{\mathbf{i}}^{[1-s]} \leq v_\rho^2 \right)}{\mathbb{P}\left(v_\rho < M_{\mathbf{i}} \leq v_\rho^2 \right)} \cdot \mathbb{P}\left(N_{C(\mathbf{i})}(v_\rho) = k, M_{C(\mathbf{i})} \leq v_\rho^2, S(K, K') < s, Y_s \wedge K' = K' \right) \\
& + \left| \frac{\mathbb{P}\left(v_\rho < M_{\mathbf{i}}^{[1-s]} \leq v_\rho^2 \right)}{\mathbb{P}\left(v_\rho < M_{\mathbf{i}} \leq v_\rho^2 \right)} - 1 \right| \cdot \mathbb{P}\left(N_{C(\mathbf{i})}(v_\rho) = k, M_{C(\mathbf{i})} \leq v_\rho^2 \right) \\
& + \frac{\mathbb{P}\left(v_\rho < M_{\mathbf{i}}^{[1-s]} \leq v_\rho^2 \right)}{\mathbb{P}\left(v_\rho < M_{\mathbf{i}} \leq v_\rho^2 \right)} \cdot \mathbb{P}\left(\{N_{C(\mathbf{i})}(v_\rho) = k, M_{C(\mathbf{i})} \leq v_\rho^2\} \cap \{S(K, K') < s, Y_s \wedge K' = K'\}^c \right).
\end{aligned}
$$

Notice that in the above equation we have considered the sets $\mathbf{i}$ and $C(\mathbf{i})$ instead of the sets $\mathbf{i}^\circ$ and $C(\mathbf{i})^\circ$, which appear in Lemma 3.5. Actually, this does not modify the probability which are considered because a.s. no incenter of a cell is located at the boundary of $\mathbf{i}$ or of $C(\mathbf{i})$ respectively. Now, summing over $k \geq 0$ and using the fact that $\sum_{k=0}^{\infty} \mathbb{P}\left(N_{C(\mathbf{i})}(v_\rho) = k \right) = 1$, we have

$$
\begin{aligned}
\sum_{k=0}^{\infty} p_{k,\mathbf{i}} \leq\ & \mathbb{P}\left(M_{C(\mathbf{i})} \leq v_\rho^2 | v_\rho < M_{\mathbf{i}} \leq v_\rho^2 \right) \\
& - \frac{\mathbb{P}\left(v_\rho < M_{\mathbf{i}}^{[1-s]} \leq v_\rho^2 \right)}{\mathbb{P}\left(v_\rho < M_{\mathbf{i}} \leq v_\rho^2 \right)} \cdot \mathbb{P}\left(M_{C(\mathbf{i})} \leq v_\rho^2, S(K, K') < s, Y_s \wedge K' = K' \right) \\
& + \left| \frac{\mathbb{P}\left(v_\rho < M_{\mathbf{i}}^{[1-s]} \leq v_\rho^2 \right)}{\mathbb{P}\left(v_\rho < M_{\mathbf{i}} \leq v_\rho^2 \right)} - 1 \right| \cdot \mathbb{P}\left(M_{C(\mathbf{i})} \leq v_\rho^2 \right) \\
& + \frac{\mathbb{P}\left(v_\rho < M_{\mathbf{i}}^{[1-s]} \leq v_\rho^2 \right)}{\mathbb{P}\left(v_\rho < M_{\mathbf{i}} \leq v_\rho^2 \right)} \cdot \mathbb{P}\left(\{M_{C(\mathbf{i})} \leq v_\rho^2\} \cap \{S(K, K') < s, Y_s \wedge K' = K'\}^c \right).
\end{aligned}
$$

Bounding the probabilities $\mathbb{P}\left(M_{C(\mathbf{i})} \leq v_\rho^2 | v_\rho < M_{\mathbf{i}} \leq v_\rho^2 \right)$ and $\mathbb{P}\left(M_{C(\mathbf{i})} \leq v_\rho^2 \right)$ by 1 respectively, and using the trivial inequalities

$$
\mathbb{P}\left(\{M_{C(\mathbf{i})} \leq v_\rho^2\} \cap \{S(K, K') < s, Y_s \wedge K' = K'\}^c \right) \leq \mathbb{P}\left(\{S(K, K') < s, Y_s \wedge K' = K'\}^c \right)
$$

and

$$\mathbb{P}\left(M_{C(\mathbf{i})} \le v_\rho^2, S(K, K') < s, Y_s \wedge K' = K'\right) \ge \mathbb{P}\left(S(K, K') < s, Y_s \wedge K' = K'\right) - \mathbb{P}\left(M_{C(\mathbf{i})} > v_\rho^2\right),$$

we obtain

$$\sum_{k=0}^{\infty} p_{k,\mathbf{i}} \le 1 - \frac{\mathbb{P}\left(v_\rho < M_{\mathbf{i}}^{[1-s]} \le v_\rho^2\right)}{\mathbb{P}\left(v_\rho < M_{\mathbf{i}} \le v_\rho^2\right)} \cdot \left(\mathbb{P}\left(S(K, K') < s, Y_s \wedge K' = K'\right) - \mathbb{P}\left(M_{C(\mathbf{i})} > v_\rho^2\right)\right)$$
$$+ \left|\frac{\mathbb{P}\left(v_\rho < M_{\mathbf{i}}^{[1-s]} \le v_\rho^2\right)}{\mathbb{P}\left(v_\rho < M_{\mathbf{i}} \le v_\rho^2\right)} - 1\right| + \frac{\mathbb{P}\left(v_\rho < M_{\mathbf{i}}^{[1-s]} \le v_\rho^2\right)}{\mathbb{P}\left(v_\rho < M_{\mathbf{i}} \le v_\rho^2\right)} \cdot \mathbb{P}\left(\{S(K, K') < s, Y_s \wedge K' = K'\}^c\right).$$

Analogously to (5.3), and applying (1.2), (1.5), and the fact that $a(C(\mathbf{i})) = O(\rho)$ we obtain that

$$\mathbb{P}\left(M_{C(\mathbf{i})} > v_\rho^2\right) \le \mathbb{E}\left[\sum_{\mathbf{j} \in C(\mathbf{i})} \mathbf{1}_{M_{\mathbf{j}} > v_\rho^2}\right] = \gamma_1 \, a(C(\mathbf{i})) \, \mathbb{P}\left(R(\mathcal{Z}) > v_\rho^2\right) = O(\rho^{-\frac{1}{2}\log \rho + \log \tau + 1}),$$

which converges to 0 as ρ goes to infinity. Thus, to prove that $\sum_{k=0}^{\infty} p_{k,\mathbf{i}}$ converges to 0, it is sufficient to choose s, as a function of ρ, in such a way that the following properties hold:

$$\frac{\mathbb{P}\left(v_\rho < M_{\mathbf{i}}^{[1-s]} \le v_\rho^2\right)}{\mathbb{P}\left(v_\rho < M_{\mathbf{i}} \le v_\rho^2\right)} \xrightarrow[\rho \to \infty]{} 1 \tag{5.5}$$

and

$$\mathbb{P}\left(S(K, K') < s, Y_s \wedge K' = K'\right) \xrightarrow[\rho \to \infty]{} 1. \tag{5.6}$$

To do it, we choose $s = \rho^{-\delta}$ with $0 < \delta < \beta/2$.

First, we prove (5.5). Analogously to (5.3), for $u = 1, 1 - s$ and $k = 1, 2$, we have $\mathbb{P}\left(M_{\mathbf{i}}^{[u]} > v_\rho^k\right) = a(\mathbf{i})\gamma_u e^{-2uv_\rho^k}$, with $\rho > \rho_0(\tau)$. Since $\gamma_u = \frac{u^2}{\pi}$, this gives

$$\frac{\mathbb{P}\left(v_\rho < M_{\mathbf{i}}^{[1-s]} \le v_\rho^2\right)}{\mathbb{P}\left(v_\rho < M_{\mathbf{i}} \le v_\rho^2\right)} = \frac{[1-s]^2 \left(e^{-2[1-s]v_\rho} - e^{-2[1-s]v_\rho^2}\right)}{e^{-2v_\rho} - e^{-2v_\rho^2}}.$$

This together with the fact that $s \, v_\rho^2 \xrightarrow[\rho \to \infty]{} 0$ shows (5.5).

It remains to prove (5.6). To do it, we apply an inequality established in [10]. We first recall the framework of this paper. Let a be the length of the side of the square (centered at the origin) $K = \left(\bigcup_{\mathbf{j} \in S(\mathbf{i}, \rho^{\beta/2})} \mathbf{j}\right) \ominus \mathbf{S}_0$. It is clear that

$$a = \sqrt{a(\mathbf{i})}(2\lfloor \rho^{\frac{\beta}{2}} \rfloor + 1) - 2v_\rho^2 \tag{5.7}$$

for some constant c. Let $f_1 = [-\frac{a}{2}, \frac{a}{2}] \times \{\frac{a}{2}\}$, $f_2 = \{\frac{a}{2}\} \times [-\frac{a}{2}, \frac{a}{2}]$, $f_3 = -f_1$ and $f_4 = -f_2$ be the sides of K. Similarly, with the same orientation, we denote by f_1', f_2', f_3', f_4' the sides of the square (centered at the origin) $K' = \mathbf{i} \oplus \mathbf{S}_0$. The length of each side of K' is

$$a' = \sqrt{a(\mathbf{i})} + 2v_\rho^2. \tag{5.8}$$

21

Now, let $L(K, K') := \min\{\Lambda([f_i|f_i']) : i = 1, \ldots, 4\}$, as in equation (13) of [10]. Notice that the quantities $\Lambda([f_i|f_i'])$ appearing in this minimum actually do not depend on i because Λ is invariant under rotation. Equation (18) of [10] states the following inequality:

$$\mathbb{P}\left(S(K, K') < s, Y_s \wedge K' = K'\right) \geq e^{-s\Lambda[K']}\left(1 - e^{-sL(K,K')}\right)^4.$$

To calculate $L(K, K')$, consider the trapezoid spanned by f_1 and f_1' (see Figure 1). A line H separates f_1 and f_1', if and only if it intersects the two nonparallel sides of the trapezoid. Denote by ℓ the length of a diagonal of the trapezoid. The distance between f_1 and f_1' is $\frac{1}{2}(a - a')$. A formula for the measure of all lines intersecting two planar compact convex sets can be found in [17], p. 33. Applying this to the linear segments f_1, f_1', we obtain with some elementary geometry that

$$L(K, K') = 2\ell - (a + a') = \sqrt{2}\sqrt{a^2 + a'^2} - (a + a') \geq (\sqrt{2} - 1)a - a'.$$

According to (5.7) and (5.8), this gives

$$
\begin{aligned}
L(K, K') &\geq (\sqrt{2} - 1)\left(\sqrt{a(\mathbf{i})}(2\lfloor\rho^{\frac{\beta}{2}}\rfloor + 1) - 2v_\rho^2\right) - (\sqrt{a(\mathbf{i})} + 2v_\rho^2)\\
&= \left((\sqrt{2} - 1)(2\lfloor\rho^{\frac{\beta}{2}}\rfloor + 1) - 1\right)\sqrt{a(\mathbf{i})} - 2\sqrt{2}v_\rho^2\\
&\geq 2(\sqrt{2} - 1)\rho^{\frac{\beta}{2}} - \sqrt{2} - 2\sqrt{2}v_\rho^2,
\end{aligned}
$$

where the second inequality comes from the facts that $\sqrt{a(\mathbf{i})} \geq 1$ (when ρ is sufficiently large) and $\lfloor\rho^{\frac{\beta}{2}}\rfloor \geq \rho^{\frac{\beta}{2}} - 1$. Using the fact that $\sqrt{2} \leq (\sqrt{2} - 1)\rho^{\frac{\beta}{2}}$ (for ρ sufficiently large), we get

$$
\begin{aligned}
L(K, K') &\geq 2(\sqrt{2} - 1)\rho^{\frac{\beta}{2}} - (\sqrt{2} - 1)\rho^{\frac{\beta}{2}} - 2\sqrt{2}v_\rho^2\\
&= (\sqrt{2} - 1)\rho^{\frac{\beta}{2}} - 2\sqrt{2}v_\rho^2.
\end{aligned}
$$

Since $s = \rho^{-\delta}$ with $0 < \delta < \beta/2$, we obtain that $s\,L(K, K') \xrightarrow[\rho\to\infty]{} \infty$. Furthermore, $s\Lambda[K'] = \frac{4}{\pi}s\,a'$, which converges to 0 as ρ goes to infinity. This shows (5.6). Consequently, b_3 converges to 0 as ρ goes to infinity, which completes the proof of Theorem 1.1.

6   Concluding remarks

In this section, we discuss some possible extensions of Theorem 1.1. First, in the proof of our main theorem, it is essential that the considered random tessellation is stationary. Such a condition is standard in Stochastic Geometry, and is classical in Extreme Value Theory. Another assumption is that our STIT tessellation is isotropic. This is used in the proof of Lemma 3.1 and in the computation of $L(K, K')$ (see p. 22). However, our results can be extended to non-isotropic STIT tessellations, as long as the directional distribution of the dividing lines are atomless, and hence no parallel sides occur in the tessellation. The asymptotic behaviour of the largest order statistics is the same as in Theorem 1.1, especially because (1.2) remains true for stationary but non-isotropic STIT tessellations. If there are cells with pairs of parallel sides, their incircles must not be unique, and a different approach to the problem is required.
Figure 1: The sides f_1, f_1' of the squares K, K', and the associated trapezoid

Our main theorem is given specifically for the two dimensional case with a fixed square-shaped window W_ρ in order to keep our calculations simple. However, Theorem 1.1 remains true when the window is any convex body with non-empty interior. We conjecture that our results concerning the largest order statistics may be extended to higher dimensions.

We now compare our method to the one used in [4]. As mentioned on p. 3, our result is similar to Theorem 1.1 (ii) of [4]. However, the proof of this theorem is based on the method of moments, which leads to very technical computations of combinatorics, and does not provide rate of convergence for the Poisson approximation. On the opposite, our proof based on the Chen-Stein method, is more accurate in the sense that the rate of convergence can be made explicit. In Theorem 1.1 (i) of [4], the smallest order statistics for the inradius are also considered. We did not investigate this problem in the context of STIT tessellations because it relies on a simple adaptation of [4]. The method is similar and is mainly based on the study of U-statistics, which are investigated in [19].
