

Categorical structures enriched in a quantaloid: categories, distributors and functors

Isar Stubbe*

May 10, 2004

Abstract

We thoroughly treat several familiar and less familiar definitions and results concerning categories, functors and distributors enriched in a base quantaloid \mathcal{Q} . In analogy with \mathcal{V} -category theory we discuss such things as adjoint functors, (pointwise) left Kan extensions, weighted (co)limits, presheaves and free (co)completion, Cauchy completion and Morita equivalence. With an appendix on the universality of the quantaloid $\text{Dist}(\mathcal{Q})$ of \mathcal{Q} -enriched categories and distributors.

1 Introduction

The theory of categories enriched in a symmetric monoidal closed category \mathcal{V} is, by now, well known [Bénabou, 1963, 1965; Eilenberg and Kelly, 1966; Lawvere, 1973; Kelly, 1982]. For such a \mathcal{V} with “enough” (co)limits the theory of \mathcal{V} -categories, distributors and functors can be pushed as far as needed: it includes such things as (weighted) (co)limits in a \mathcal{V} -category, \mathcal{V} -presheaves on a \mathcal{V} -category, Kan extensions of enriched functors, Morita theory for \mathcal{V} -categories, and so on.

Monoidal categories are precisely one-object bicategories [Bénabou, 1967]. It is thus natural to ask in how far \mathcal{V} -category theory can be generalized to \mathcal{W} -category theory, for \mathcal{W} a general bicategory. But, whereas in \mathcal{V} -category theory one usually assumes the symmetry of the tensor in \mathcal{V} (which is essential to show that \mathcal{V} is itself a \mathcal{V} -category with hom-objects given by the right adjoint to tensoring), in working over a general bicategory \mathcal{W} we will have to sacrifice this symmetry: tensoring objects in \mathcal{V} corresponds to composing morphisms in \mathcal{W} and in general it simply does not make sense for the composition $g \circ f$ of two arrows f, g to be “symmetric”.

On the other hand, we can successfully translate the notion of closedness of a monoidal category \mathcal{V} to the more general setting of a bicategory \mathcal{W} : ask that, for

*Département de Mathématique, Université de Louvain, Chemin du Cyclotron 2, 1348 Louvain-la-Neuve (Belgique), i.stubbe@math.ucl.ac.be.

any object X of \mathcal{W} and any arrow $f : A \rightarrow B$ in \mathcal{W} , both functors

$$- \circ f : \mathcal{W}(B, X) \rightarrow \mathcal{W}(A, X) : x \mapsto x \circ f, \quad (1)$$

$$f \circ - : \mathcal{W}(X, A) \rightarrow \mathcal{W}(X, B) : x \mapsto f \circ x \quad (2)$$

have respective right adjoints

$$\{f, -\} : \mathcal{W}(A, X) \rightarrow \mathcal{W}(B, X) : y \mapsto \{f, y\}, \quad (3)$$

$$[f, -] : \mathcal{W}(X, B) \rightarrow \mathcal{W}(X, A) : y \mapsto [f, y]. \quad (4)$$

Such a bicategory \mathcal{W} is said to be closed. Some call an arrow such as $\{f, y\}$ a (right) extension and $[f, y]$ a (right) lifting (of y through f).

Finally, by saying that \mathcal{V} has “enough limits and colimits” is in practice often meant that \mathcal{V} has small limits and small colimits. In a bicategory \mathcal{W} the analogue is straightforward: now ask for \mathcal{W} to have in its hom-categories small limits and small colimits (i.e. \mathcal{W} is locally complete and cocomplete).

So, to summarize, when trying to develop category theory over a base bicategory \mathcal{W} rather than a base monoidal category \mathcal{V} , it seems reasonable to work with a base bicategory which is closed, locally complete and locally cocomplete. Note that in such a bicategory \mathcal{W} , due to its closedness, composition always distributes on both sides over colimits of morphisms:

$$f \circ (\operatorname{colim}_{i \in I} g_i) \cong \operatorname{colim}_{i \in I} (f \circ g_i), \quad (5)$$

$$(\operatorname{colim}_{j \in J} f_j) \circ g \cong \operatorname{colim}_{j \in J} (f_j \circ g). \quad (6)$$

That is to say, the local colimits are stable under composition. (But this does not hold in general for local limits!)

We will focus on a special case of these closed, locally complete and locally cocomplete bicategories: namely, we study such bicategories whose hom-categories are moreover small and skeletal. Thus the hom-categories are simply complete lattices. We will write the local structure as an order, and local limits and colimits of morphisms as their infimum, resp. supremum—so for arrows with same domain and codomain we have things like $f \leq f'$, $\bigvee_{i \in I} f_i$, $\bigwedge_{j \in J} g_j$, etc. In particular (5) and (6) become

$$f \circ (\bigvee_i g_i) = \bigvee_i (f \circ g_i), \quad (7)$$

$$(\bigvee_j f_j) \circ g = \bigvee_j (f_j \circ g). \quad (8)$$

The adjoint functor theorem says that the existence of the adjoints (3) and (4) to the composition functors (1) and (2) (not only implies but also) is implied by their distributing over suprema of morphisms as in (7) and (8). Such bicategories – whose hom-categories are complete lattices and whose composition distributes on both sides over arbitrary suprema – are called quantaloids. A one-object quantaloid

is a quantale¹. So a quantaloid \mathcal{Q} is a \mathbf{Sup} -enriched category (and a quantale is monoid in \mathbf{Sup}).

We will argue below that “ \mathcal{V} -category theory” can be generalized to “ \mathcal{Q} -category theory”, where now \mathcal{Q} denotes a quantaloid. This is a particular case of the theory of “ \mathcal{W} -category theory” as pioneered by [Bénabou, 1967; Walters, 1981; Street, 1983a]. But we feel that this particular case is also of particular interest: many examples of bicategory-enriched categories are really quantaloid-enriched. In our further study of categorical structures enriched in a quantaloid we rely heavily on the basic theory of \mathcal{Q} -categories, distributors and functors; however, often we could not find an appropriate reference for one or another basic fact. With this text we wish to provide such a reference.

A first further study, in [Stubbe, 2004a], is concerned with “variation and enrichment”, in the sense of [Betti *et al.*, 1983; Gordon and Power, 1997, 1999]. This is a development of the notion of weighted colimit in a \mathcal{Q} -enriched category; in particular, a tensored and cotensored \mathcal{Q} -category has all weighted colimits (as in section 5 below) if and only if it has all conical colimits, if and only if its underlying order has suprema of objects of the same type. This allows for a detailed analysis of the biequivalence between \mathcal{Q} -modules and cocomplete \mathcal{Q} -categories.

The subject of [Stubbe, 2004b] is that of presheaves on \mathcal{Q} -semicategories (“categories without units”), along the lines of [Moens *et al.*, 2002]; it generalizes the theory of regular modules on rings without units. The point is that certain “good properties” of the Yoneda embedding for \mathcal{Q} -categories (see section 6 below) are no longer valid for \mathcal{Q} -semicategories—for example, a presheaf on a \mathcal{Q} -semicategory is not canonically the weighted colimit of representables. Enforcing precisely this latter condition defines what is called a “regular presheaf” on a \mathcal{Q} -semicategory; there is an interesting theory of “regular \mathcal{Q} -semicategories”.

[Borceux and Cruciani, 1998] gives an elementary description of ordered objects in the topos of sheaves on a locale Ω . This turns out to be all about enriched Ω -semicategories that admit an appropriate Cauchy completion. In [Stubbe, 2004c] we describe more generally the theory of \mathcal{Q} -semicategories that admit a well-behaved Cauchy completion, that we want to call “ \mathcal{Q} -orders” (based on the material in section 7). Such \mathcal{Q} -orders can equivalently be described as categories enriched in the split-idempotent completion of \mathcal{Q} , and so provide a “missing link” between [Walters, 1981] and [Borceux and Cruciani, 1998].

¹It was C. Mulvey [1986] who introduced the word ‘quantale’ in his work on (non-commutative) C^* -algebras as a contraction of ‘quantum’ and ‘locale’.

2 Quantaloids

A sup-lattice is an antisymmetrically ordered set² (X, \leq) for which every subset $X' \subseteq X$ has a supremum $\bigvee X'$ in X . A morphism of sup-lattices $f: (X, \leq) \rightarrow (Y, \leq)$ is a map $f: X \rightarrow Y$ that preserves arbitrary suprema. It is well-known that sup-lattices and sup-morphisms constitute a symmetric monoidal closed category \mathbf{Sup} .

Definition 2.1 A quantaloid \mathcal{Q} is a \mathbf{Sup} -enriched category. A homomorphism $F: \mathcal{Q} \rightarrow \mathcal{Q}'$ of quantaloids is a \mathbf{Sup} -enriched functor.

In principle we don't mind a quantaloid having a proper class of objects. Thus quantaloids and homomorphisms form an illegitimate category \mathbf{QUANT} ; small quantaloids define a (true) subcategory \mathbf{Quant} . A quantaloid with one object is often thought of as a monoid in \mathbf{Sup} , and is called a *quantale*.

In elementary terms, a quantaloid \mathcal{Q} is a category whose hom-sets are actually sup-lattices, in which composition distributes on both sides over arbitrary suprema of morphisms. In the same vein, a homomorphism $F: \mathcal{Q} \rightarrow \mathcal{Q}'$ is a functor of (the underlying) categories that preserves arbitrary suprema of morphisms.

For arrows $f: A \rightarrow B$, $g: B \rightarrow C$, $(h_i: X \rightarrow Y)_{i \in I}$ in a quantaloid \mathcal{Q} we use notations like $g \circ f: A \rightarrow C$ for composition, and $\bigvee_i h_i: X \rightarrow Y$ and $h_i \leq h_j: X \rightrightarrows Y$ for its local structure; $\mathcal{Q}(A, B)$ is the hom-lattice of arrows from A to B . The identity arrow on an object $A \in \mathcal{Q}$ is written $1_A: A \rightarrow A$. The bottom element of a sup-lattice $\mathcal{Q}(A, B)$ will typically be denoted by $0_{A,B}$. With these notations for identity and bottom, we can write a ‘‘Kronecker delta’’

$$\delta_{A,B}: A \rightarrow B = \begin{cases} 1_A: A \rightarrow A & \text{if } A = B, \\ 0_{A,B}: A \rightarrow B & \text{otherwise.} \end{cases}$$

As we may consider \mathbf{Sup} to be a ‘‘simplified version of \mathbf{Cat} ’’, we may regard quantaloids as ‘‘simplified bicategories’’. Notably, a quantaloid \mathcal{Q} has small hom-categories with stable local colimits, and therefore it is closed. Considering morphisms $f: A \rightarrow B$ and $g: B \rightarrow C$ we note the respective adjoints to composition in \mathcal{Q} as $- \circ f \dashv \{f, -\}$ and $g \circ - \dashv [g, -]$; that is to say, for any $h: A \rightarrow C$ we have that $g \circ f \leq h$ iff $\leq [g, h]$ iff $g \leq \{f, h\}$. Note furthermore that every diagram of 2-cells in a quantaloid trivially commutes.

There are a couple of lemmas involving $[-, -]$ and $\{-, -\}$, that hold in any quantaloid, upon which we rely quite often. Let us give a short overview.

Lemma 2.2 *We work in a quantaloid \mathcal{Q} .*

1. For $f: A \rightarrow B$, $g: B \rightarrow C$ and $h: A \rightarrow C$, $[g, h] = \bigvee \{x: A \rightarrow B \mid g \circ x \leq h\}$ and $\{f, h\} = \bigvee \{y: B \rightarrow C \mid y \circ f \leq h\}$.

²By an ‘‘ordered set’’ we mean a set endowed with a transitive, reflexive relation; it is what is often called a ‘‘preordered set’’. We will be explicit when we mean one such relation that is moreover antisymmetric, i.e. a ‘‘partial order’’.

2. The following are equivalent:

- (a) $f \dashv g: B \overset{\leftarrow}{\dashv} A$ in \mathcal{Q} (i.e. $1_A \leq g \circ f$ and $f \circ g \leq 1_B$);
- (b) $(f \circ -) \dashv (g \circ -): \mathcal{Q}(-, B) \overset{\leftarrow}{\dashv} \mathcal{Q}(-, A)$ in \mathbf{Sup} ;
- (c) $(- \circ g) \dashv (- \circ f): \mathcal{Q}(B, -) \overset{\leftarrow}{\dashv} \mathcal{Q}(A, -)$ in \mathbf{Sup} ;
- (d) $(g \circ -) = [f, -]: \mathcal{Q}(-, B) \rightarrow \mathcal{Q}(-, A)$ in \mathbf{Sup} ;
- (e) $(- \circ f) = \{g, -\}: \mathcal{Q}(B, -) \rightarrow \mathcal{Q}(A, -)$ in \mathbf{Sup} .

3. An arrow $f: A \rightarrow B$ has a right adjoint if and only if $[f, 1_B] \circ f = [f, f]$; in this case the right adjoint to f is $[f, 1_B]$. Dually, $g: B \rightarrow A$ in \mathcal{Q} has a left adjoint if and only if $g \circ \{g, 1_B\} = \{g, g\}$; in this case the left adjoint to g is $\{g, 1_B\}$.

4. For $f, f': A \rightrightarrows B$ and $g, g': B \rightrightarrows A$ such that $f \dashv g$ and $f' \dashv g'$, $f \leq f'$ if and only if $g' \leq g$.

5. Any $f: A \rightarrow B$ induces, for every $X \in \mathcal{Q}_0$, an adjunction

$$[-, f] \dashv \{-, f\}: \mathcal{Q}(X, B) \overset{\leftarrow}{\dashv} \mathcal{Q}(A, X)^{\text{op}}.$$

By $\mathcal{Q}(A, X)^{\text{op}}$ is meant the sup-lattice $\mathcal{Q}(A, X)$ with opposite order.

6. For arrows with suitable domain and codomain we have the (dual) identities $[f, [g, h]] = [g \circ f, h]$ and $\{k, \{m, n\}\} = \{k \circ m, n\}$, and the (self-dual) identity $[x, \{y, z\}] = \{z, [x, y]\}$.

7. For arrows with suitable domain and codomain, $[h, g] \circ [g, f] \leq [h, f]$ and dually $\{l, m\} \circ \{k, l\} \leq \{k, m\}$; also $1_{\text{dom}(f)} \leq [f, f]$ and dually $1_{\text{cod}(f)} \leq \{f, f\}$.

\mathbf{Sup} may also be thought of as an “infinitary version of \mathbf{Ab} ”; a quantaloid is then like a “ring(oid) with infinitary (and idempotent) sum”. This point of view helps to explain some of the terminology below—especially when we talk about “matrices with elements in a quantaloid \mathcal{Q} ” in the appendix.

Example 2.3 Any locale Ω is a (very particular) quantale. Further on we’ll denote $\mathbf{2}$ for the two-element boolean algebra. Given a locale Ω , [Walters, 1981] uses the quantaloid of relations in Ω : the objects of $\mathbf{Rel}(\Omega)$ are the elements of Ω , the hom-lattices are given by $\mathbf{Rel}(\Omega)(u, v) = \{w \in \Omega \mid w \leq u \wedge v\}$ with order inherited from Ω , composition is given by infimum in Ω , and the identity on an object u is u itself. This quantaloid is very particular: it equals its opposite.

Example 2.4 The extended non-negative reals $\mathbb{R}^+ \cup \{+\infty\}$ form a (symmetric) quantale for the opposite order and addition as binary operation [Lawvere, 1973].

Example 2.5 The ideals in a commutative ring R form a (symmetric) quantale. When R is not commutative, the two-sided ideals still form a (symmetric) quantale. But, as G. Van den Bossche [1995] points out (but she credits B. Lawvere for this idea), there is also quite naturally a “quantaloid of ideals” containing a lot more information than just the two-sided ideals. Denoting \mathcal{Q}_R for this structure, define that it has two objects, 0 and 1; the hom-sup-lattices are

$$\begin{aligned}\mathcal{Q}_R(0, 0) &= \text{additive subgroups of } R \text{ which are } \mathcal{Z}(R)\text{-modules,} \\ \mathcal{Q}_R(0, 1) &= \text{left-sided ideals of } R, \\ \mathcal{Q}_R(1, 0) &= \text{right-sided ideals of } R, \\ \mathcal{Q}_R(1, 1) &= \text{two-sided ideals of } R,\end{aligned}$$

with sum of additive subgroups as supremum:

$$\sum_{k \in K} I_k = \{\text{finite sums of elements in } \bigcup_{k \in K} I_k\}.$$

Composition in \mathcal{Q}_R is the multiplication of additive subgroups, as in

$$I \circ J = \{\text{finite sums } i_1 j_1 + \dots + i_n j_n \text{ with all } i_k \in I \text{ and all } j_k \in J\};$$

and the identity arrow on 1 is R and that on 0 is $\mathcal{Z}(R)$. (By $\mathcal{Z}(R)$ we denote the center of R). For a commutative R , this quantaloid \mathcal{Q}_R is equivalent as **Sup**-category to the quantale of ideals in R .

More examples can be found in the literature, e.g. [Rosenthal, 1996].

3 Three basic definitions

In the following \mathcal{Q} always denotes a quantaloid. By a \mathcal{Q} -typed set X we mean a set X to every element of which is associated an object of \mathcal{Q} : for every $x \in X$ there is a tx in \mathcal{Q} (which is called the *type* of x in \mathcal{Q}). The notation with a “ t ” for the types of elements in a \mathcal{Q} -typed set is generic; i.e. even for two different \mathcal{Q} -typed sets X and Y , the type of an $x \in X$ is written tx , and that of a $y \in Y$ is ty . A \mathcal{Q} -typed set X is just a way of writing a set-indexed family $(tx)_{x \in X}$ of objects (i.e. a small discrete diagram) in \mathcal{Q} . If \mathcal{Q} is a small quantaloid, then a \mathcal{Q} -typed set is an object of the slice category $\mathbf{Set}/\mathcal{Q}_0$.

Definition 3.1 A \mathcal{Q} -enriched category (or \mathcal{Q} -category for short) \mathbb{A} consists of

- objects: a \mathcal{Q} -typed set \mathbb{A}_0 ,
- hom-arrows: for all $a, a' \in \mathbb{A}_0$, an arrow $\mathbb{A}(a', a): ta \longrightarrow ta'$ in \mathcal{Q} ,

satisfying

- *composition-inequalities*: for all $a, a', a'' \in \mathbb{A}_0$, $\mathbb{A}(a'', a') \circ \mathbb{A}(a', a) \leq \mathbb{A}(a'', a)$ in \mathcal{Q} ,
- *identity-inequalities*: for all $a \in \mathbb{A}_0$, $1_{ta} \leq \mathbb{A}(a, a)$ in \mathcal{Q} .

Definition 3.2 A distributor $\Phi: \mathbb{A} \dashrightarrow \mathbb{B}$ between two \mathcal{Q} -categories is given by

- *distributor-arrows*: for all $a \in \mathbb{A}_0$, $b \in \mathbb{B}_0$, an arrow $\Phi(b, a): ta \rightarrow tb$ in \mathcal{Q}

satisfying

- *action-inequalities*: for all $a, a' \in \mathbb{A}_0$, $b, b' \in \mathbb{B}_0$, $\mathbb{B}(b', b) \circ \Phi(b, a) \leq \Phi(b', a)$ and $\Phi(b, a) \circ \mathbb{A}(a, a') \leq \Phi(b, a')$ in \mathcal{Q} .

Definition 3.3 A functor $F: \mathbb{A} \rightarrow \mathbb{B}$ between \mathcal{Q} -categories is

- *object-mapping*: a map $F: \mathbb{A}_0 \rightarrow \mathbb{B}_0: a \mapsto Fa$

satisfying

- *type-equalities*: for all $a \in \mathbb{A}_0$, $ta = t(Fa)$ in \mathcal{Q} ,
- *action-inequalities*: for all $a, a' \in \mathbb{A}_0$, $\mathbb{A}(a', a) \leq \mathbb{B}(Fa', Fa)$ in \mathcal{Q} .

None of these definitions requires any of the usual diagrammatic axioms (associativity and identity axioms for the composition in a category, coherence of the action on a distributor with the composition in its (co)domain category, the functoriality of a functor) simply because those conditions, which require the commutativity of certain diagrams of 2-cells in the base quantaloid \mathcal{Q} , hold trivially! It is therefore a property of, rather than an extra structure on, a given set \mathbb{A}_0 of elements with types in \mathcal{Q} together with hom-arrows $\mathbb{A}(a', a): ta' \rightarrow ta$ (for $a, a' \in \mathbb{A}_0$) to be a \mathcal{Q} -category; in other words, if these data determine a \mathcal{Q} -category, then they do so in only one way. Similar for distributors and functors: it is a property of a given collection of arrows $\Phi(b, a): ta \rightarrow tb$ whether or not it determines a distributor between \mathcal{Q} -categories \mathbb{A} and \mathbb{B} , as it is a property of an object mapping $F: \mathbb{A}_0 \rightarrow \mathbb{B}_0$ whether or not it determines a functor.

Our \mathcal{Q} -categories are by definition small: they have a set of objects. As a consequence, the collection of distributors between two \mathcal{Q} -categories is always a small set too, and so is the collection of functors between two \mathcal{Q} -categories. (However, we will soon run into size-related trouble: our base quantaloid \mathcal{Q} having a proper class of objects will conflict with the \mathcal{Q} -categories being small, in particular in matters related to cocompleteness of \mathcal{Q} -categories. When doing categorical algebra over \mathcal{Q} we will therefore suppose that \mathcal{Q} is small too. But this hypothesis is not necessary at this point.)

Note that for a distributor $\Phi: \mathbb{A} \dashrightarrow \mathbb{B}$, for all $a \in \mathbb{A}$ and $b \in \mathbb{B}$,

$$\Phi(b, a) = 1_{tb} \circ \Phi(b, a) \leq \mathbb{B}(b, b) \circ \Phi(b, a) \leq \bigvee_{b' \in \mathbb{B}} \mathbb{B}(b, b') \circ \Phi(b', a) \leq \Phi(b, a),$$

that is to say, $\bigvee_{b' \in \mathbb{B}} \mathbb{B}(b, b') \circ \Phi(b', a) = \Phi(b, a)$; $\bigvee_{a' \in \mathbb{A}} \Phi(b, a') \circ \mathbb{A}(a', a) = \Phi(b, a)$ is analogous. A \mathcal{Q} -category \mathbb{A} is itself a distributor from \mathbb{A} to \mathbb{A} ; and the identities above become, for all $a, a'' \in \mathbb{A}$, $\bigvee_{a' \in \mathbb{A}} \mathbb{A}(a'', a') \circ \mathbb{A}(a', a) = \mathbb{A}(a'', a)$. These identities allow to say, in 3.4, with a suitable definition for the composition of distributors, that “ \mathbb{A} is the identity distributor on \mathbb{A} ”.

There is a notational issue that we should comment on. We have chosen to write the composition of arrows in a base quantaloid \mathcal{Q} “from right to left”: the composite of $f: X \rightarrow Y$ and $g: Y \rightarrow Z$ is $g \circ f: X \rightarrow Z$. Therefore we have chosen to write the hom-arrows in a \mathcal{Q} -enriched category \mathbb{A} also “from right to left”: for two objects $a, a' \in \mathbb{A}$, the hom-arrow $\mathbb{A}(a', a)$ goes from ta to ta' . Doing so it is clear that, for example, the composition-inequality in \mathbb{A} is written $\mathbb{A}(a'', a') \circ \mathbb{A}(a', a) \leq \mathbb{A}(a'', a)$, with the *pivot* a' nicely in the middle, which we find very natural. Our notational conventions are thus basically those of R. Street’s seminal paper [1983a]; other authors have chosen other notations.

The next proposition displays the calculus of \mathcal{Q} -categories and distributors.

Proposition 3.4 *\mathcal{Q} -categories are the objects, and distributors the arrows, of a quantaloid $\text{Dist}(\mathcal{Q})$ in which*

- the composition $\Psi \otimes_{\mathbb{B}} \Phi: \mathbb{A} \rightarrow \mathbb{C}$ of two distributors $\Phi: \mathbb{A} \rightarrow \mathbb{B}$ and $\Psi: \mathbb{B} \rightarrow \mathbb{C}$ has as distributor-arrows, for $a \in \mathbb{A}_0$ and $c \in \mathbb{C}_0$,

$$(\Psi \otimes_{\mathbb{B}} \Phi)(c, a) = \bigvee_{b \in \mathbb{B}_0} \Psi(c, b) \circ \Phi(b, a);$$

- the identity distributor on a \mathcal{Q} -category \mathbb{A} has as distributor-arrows precisely the hom-arrows of the category \mathbb{A} itself, so we simply write it as $\mathbb{A}: \mathbb{A} \rightarrow \mathbb{A}$;
- the supremum $\bigvee_{i \in I} \Phi_i: \mathbb{A} \rightarrow \mathbb{B}$ of given distributors $(\Phi_i: \mathbb{A} \rightarrow \mathbb{B})_{i \in I}$ is calculated elementwise, thus its distributor-arrows are, for $a \in \mathbb{A}_0$ and $b \in \mathbb{B}_0$,

$$\left(\bigvee_{i \in I} \Phi_i \right)(b, a) = \bigvee_{i \in I} \Phi_i(b, a).$$

The proof of the fact that the data above define a quantaloid is straightforward. Actually, $\text{Dist}(\mathcal{Q})$ is a universal construction on \mathcal{Q} in QUANT: there is a fully faithful homomorphism of quantaloids

$$\mathcal{Q} \rightarrow \text{Dist}(\mathcal{Q}): (f: A \rightarrow B) \mapsto ((f): *A \rightarrow *B) \quad (9)$$

sending an object $A \in \mathcal{Q}$ to the \mathcal{Q} -category with only one object, say $*$, of type $t^* = A$, and hom-arrow 1_A , and a \mathcal{Q} -arrow $f: A \rightarrow B$ to the distributor $(f): *A \rightarrow *B$ whose single element is f . This turns out to be the universal direct-sum-and-split-monad completion of \mathcal{Q} in QUANT. The appendix gives details. (Even for a small base quantaloid \mathcal{Q} , $\text{Dist}(\mathcal{Q})$ has a proper class of objects; so large quantaloids arise

as universal constructions on small ones. Therefore we do not wish to exclude large quantaloids *a priori*.)

Since $\text{Dist}(\mathcal{Q})$ is a quantaloid, it is in particular closed; the importance of this fact cannot be overestimated. Let for example $\Theta: \mathbb{A} \dashv\vdash \mathbb{C}$ and $\Psi: \mathbb{B} \dashv\vdash \mathbb{C}$ be distributors between \mathcal{Q} -categories, then $[\Psi, \Theta]: \mathbb{A} \dashv\vdash \mathbb{B}$ is the distributor with distributor-arrows, for $a \in \mathbb{A}_0$ and $b \in \mathbb{C}_0$,

$$[\Psi, \Theta](b, a) = \bigwedge_{c \in \mathbb{C}_0} [\Psi(c, b), \Theta(c, a)], \quad (10)$$

where the liftings on the right are calculated in \mathcal{Q} . A similar formula holds for $\{-, -\}$.

The category of \mathcal{Q} -categories and functors is the obvious one.

Proposition 3.5 *\mathcal{Q} -categories are the objects, and functors the arrows, of a category $\text{Cat}(\mathcal{Q})$ in which*

- the composition $G \circ F: \mathbb{A} \rightarrow \mathbb{C}$ of two functors $F: \mathbb{A} \rightarrow \mathbb{B}$ and $G: \mathbb{B} \rightarrow \mathbb{C}$ is determined by the composition of object maps $G \circ F: \mathbb{A}_0 \rightarrow \mathbb{C}_0: a \mapsto G(F(a))$;
- the identity functor $1_{\mathbb{A}}: \mathbb{A} \rightarrow \mathbb{A}$ on a \mathcal{Q} -category \mathbb{A} is determined by the identity object map $1_{\mathbb{A}}: \mathbb{A}_0 \rightarrow \mathbb{A}_0: a \mapsto a$.

Every functor between \mathcal{Q} -categories induces an adjoint pair of distributors, and the resulting inclusion of the functor category in the distributor category – although straightforward – is a key element for the development of the theory of \mathcal{Q} -enriched categories.

Proposition 3.6 *For \mathcal{Q} -categories and functors $F: \mathbb{A} \rightarrow \mathbb{B}$ and $G: \mathbb{C} \rightarrow \mathbb{B}$, the \mathcal{Q} -arrows $\mathbb{B}(Gc, Fa): ta \rightarrow tc$, one for each $(a, c) \in \mathbb{A}_0 \times \mathbb{C}_0$, determine a distributor³ $\mathbb{B}(G-, F-): \mathbb{A} \dashv\vdash \mathbb{C}$. In particular, for any functor $F: \mathbb{A} \rightarrow \mathbb{B}$ the distributors $\mathbb{B}(1_{\mathbb{B}}-, F-): \mathbb{A} \dashv\vdash \mathbb{B}$ and $\mathbb{B}(F-, 1_{\mathbb{B}}-): \mathbb{B} \dashv\vdash \mathbb{A}$ are adjoint in the quantaloid $\text{Dist}(\mathcal{Q})$: $\mathbb{B}(1_{\mathbb{B}}-, F-) \dashv \mathbb{B}(F-, 1_{\mathbb{B}}-)$.*

Proof: For any $a, a' \in \mathbb{A}_0$ and $c, c' \in \mathbb{C}_0$, $\mathbb{C}(c', c) \circ \mathbb{B}(Gc, Fa) \circ \mathbb{A}(a, a') \leq \mathbb{B}(Gc', Gc) \circ \mathbb{B}(Gc, Fa) \circ \mathbb{B}(Fa, Fa') \leq \mathbb{B}(Gc', Fa)$ by functoriality of F and G and composition in \mathbb{B} . So $\mathbb{B}(G-, F-)$ is a distributor from \mathbb{A} to \mathbb{B} .

To see that $\mathbb{B}(1_{\mathbb{B}}-, F-) \dashv \mathbb{B}(F-, 1_{\mathbb{B}}-)$ in $\text{Dist}(\mathcal{Q})$, we must check two inequalities: the unit of the adjunction is due to the composition in \mathbb{B} and functoriality of F , $\mathbb{B}(F-, 1_{\mathbb{B}}-) \otimes_{\mathbb{B}} \mathbb{B}(1_{\mathbb{B}}-, F-) = \mathbb{B}(F-, F-) \geq \mathbb{A}(-, -)$; the counit follows from the fact that $\{Fa \mid a \in \mathbb{A}_0\} \subseteq \mathbb{B}_0$ and – again – composition in \mathbb{B} , $\mathbb{B}(1_{\mathbb{B}}-, F-) \otimes_{\mathbb{A}} \mathbb{B}(F-, 1_{\mathbb{B}}-) \leq \mathbb{B}(1_{\mathbb{B}}-, -) \otimes_{\mathbb{B}} \mathbb{B}(-, 1_{\mathbb{B}}-) = \mathbb{B}(-, -)$. \square

In the following we use the abbreviated notations $\mathbb{B}(-, F-) = \mathbb{B}(1_{\mathbb{B}}-, F-)$ and $\mathbb{B}(F-, -) = \mathbb{B}(F-, 1_{\mathbb{B}}-)$.

³There is a converse: for any distributor $\Phi: \mathbb{A} \dashv\vdash \mathbb{C}$ there is a – universal – way in which $\Phi = \mathbb{B}(G-, F-)$ for certain functors $F: \mathbb{A} \rightarrow \mathbb{B}$ and $G: \mathbb{C} \rightarrow \mathbb{B}$.

Proposition 3.7 *Sending a functor to the left adjoint distributor that it induces, as in*

$$\text{Cat}(\mathcal{Q}) \longrightarrow \text{Dist}(\mathcal{Q}): (F: \mathbb{A} \longrightarrow \mathbb{B}) \mapsto (\mathbb{B}(-, F-): \mathbb{A} \multimap \mathbb{B}),$$

is functorial. Sending a functor to the right adjoint determines a similar contravariant functor.

Proof: Trivially an identity functor $1_{\mathbb{A}}: \mathbb{A} \longrightarrow \mathbb{A}$ is mapped onto the identity distributor $\mathbb{A}(-, 1_{\mathbb{A}}-) = \mathbb{A}(-, -): \mathbb{A} \multimap \mathbb{A}$. And if $F: \mathbb{A} \longrightarrow \mathbb{B}$ and $G: \mathbb{B} \longrightarrow \mathbb{C}$, then we want $\mathbb{C}(-, G \circ F-) = \mathbb{C}(-, G-) \otimes_{\mathbb{B}} \mathbb{B}(-, F-)$ but also this holds trivially: read the right hand side of the equation as the action of \mathbb{B} on $\mathbb{C}(-, G-)$. \square

The category $\text{Cat}(\mathcal{Q})$ inherits the local structure from the quantaloid $\text{Dist}(\mathcal{Q})$ via the functor $\text{Cat}(\mathcal{Q}) \longrightarrow \text{Dist}(\mathcal{Q})$: we put, for two functors $F, G: \mathbb{A} \multimap \mathbb{B}$,

$$F \leq G \iff \mathbb{B}(-, F-) \leq \mathbb{B}(-, G-) \quad \left(\iff \mathbb{B}(G-, -) \leq \mathbb{B}(F-, -) \right).$$

Thus every hom-set $\text{Cat}(\mathcal{Q})(\mathbb{A}, \mathbb{B})$ is (neither antisymmetrically nor cocompletely) ordered, and composition in $\text{Cat}(\mathcal{Q})$ distributes on both sides over the local order: $\text{Cat}(\mathcal{Q})$ is a 2-category, and the functor in 3.7 is a 2-functor which is the identity on objects, “essentially faithful” (but not full), and locally fully faithful. (The contravariant version of this functor reverses the local order!)

In general the “opposite” of a \mathcal{Q} -category \mathbb{A} is not again a \mathcal{Q} -category, but rather a \mathcal{Q}^{op} -category: of course \mathbb{A}^{op} is defined to have the same \mathcal{Q} -typed set of objects as \mathbb{A} , but the hom-arrows are reversed: for objects a, a' put $\mathbb{A}^{\text{op}}(a', a) = \mathbb{A}(a, a')$. Similarly, for a distributor $\Phi: \mathbb{A} \multimap \mathbb{B}$ between \mathcal{Q} -categories we may define an opposite distributor between the opposite categories over the opposite base— but this distributor will go in the opposite direction: $\Phi^{\text{op}}: \mathbb{B}^{\text{op}} \multimap \mathbb{A}^{\text{op}}$ is defined by $\Phi^{\text{op}}(a, b) = \Phi(b, a)$. For $\Phi \leq \Psi: \mathbb{A} \multimap \mathbb{B}$ in $\text{Dist}(\mathcal{Q})$ it is quite obvious that $\Phi^{\text{op}} \leq \Psi^{\text{op}}: \mathbb{B}^{\text{op}} \multimap \mathbb{A}^{\text{op}}$ in $\text{Dist}(\mathcal{Q}^{\text{op}})$. Finally, for a functor $F: \mathbb{A} \longrightarrow \mathbb{B}$ between \mathcal{Q} -categories, the *same* object mapping $a \mapsto Fa$ determines an arrow $F^{\text{op}}: \mathbb{A}^{\text{op}} \longrightarrow \mathbb{B}^{\text{op}}$ of $\text{Cat}(\mathcal{Q}^{\text{op}})$. But if $F \leq G: \mathbb{A} \multimap \mathbb{B}$ in $\text{Cat}(\mathcal{Q})$ then $G^{\text{op}} \leq F^{\text{op}}: \mathbb{A}^{\text{op}} \multimap \mathbb{B}^{\text{op}}$ in $\text{Cat}(\mathcal{Q}^{\text{op}})$. It is obvious that applying the “op” twice, always gives back the original structure.

Proposition 3.8 *“Taking opposites” determines isomorphisms*

$$\text{Dist}(\mathcal{Q}) \cong \text{Dist}(\mathcal{Q}^{\text{op}})^{\text{op}} \quad \text{and} \quad \text{Cat}(\mathcal{Q}) \cong \text{Cat}(\mathcal{Q}^{\text{op}})^{\text{co}}$$

of 2-categories (where the “co” means: reversing order in the homs).

These isomorphisms allow us to “dualize” all notions and results concerning \mathcal{Q} -enriched categories. For example, the dual of ‘left Kan extension’ in $\text{Cat}(\mathcal{Q})$ is ‘right Kan extension’, and whereas the former help to characterize left adjoints in $\text{Cat}(\mathcal{Q})$, the latter do the same for right adjoints. As another example, the dual of ‘weighted colimit’ in a \mathcal{Q} -category, is ‘weighted limit’; the former are ‘preserved’ by all left adjoint functors, the latter by right adjoint ones. Some notions are self-dual, like ‘equivalence’ of categories, or ‘Cauchy complete’ category.

Example 3.9 In a quantaloid \mathcal{Q} , the arrows whose *codomain* is some object Y are the objects of a \mathcal{Q} -category that we will denote – anticipating 6.1 – as $\mathcal{P}Y$: put $t(f: X \rightarrow Y) = X$ and $\mathcal{P}Y(f', f) = [f', f]$. Similarly – and again anticipating further results – we denote $\mathcal{P}^\dagger X$ for the \mathcal{Q} -category whose objects are \mathcal{Q} -arrows with *domain* X , with types $t(f: X \rightarrow Y) = Y$, and $\mathcal{P}^\dagger X(f', f) = \{f, f'\}$.

Example 3.10 Recall that $\mathbf{2}$ denotes the 2-element Boolean algebra; $\mathbf{2}$ -categories are orders, distributors are ideal relations, and functors are order-preserving maps.

Example 3.11 Consider a sheaf F on a locale Ω ; it determines a $\text{Rel}(\Omega)$ -category \mathbb{F} whose objects are the partial sections of F , the type of a section s being the largest $u \in \Omega$ on which it is defined, and whose hom-arrows $\mathbb{F}(s', s)$ are, for sections s, s' of types u, u' , the largest $v \leq u \wedge u'$ on which (restrictions of) s and s' agree [Walters, 1981].

Example 3.12 A category enriched in the quantale $\mathbb{R} \cup \{+\infty\}$ (cf. 2.4) is a “generalized metric space” [Lawvere, 1973]: the enrichment itself is a binary distance function taking values in the positive reals. In particular is the composition-inequality in such an enriched category the triangular inequality. A functor between such generalized metric spaces is a distance decreasing application. (These metric spaces are “generalized” in that the distance function is not symmetric, that the distance between two points being zero doesn’t imply their being identical, and that the distance between two points may be infinite.)

Example 3.13 A (not necessarily commutative) ring R determines a \mathcal{Q}_R -enriched category (with \mathcal{Q}_R as in 2.5): denoting it as Comm_R , its objects of type 0 are the elements of R , its objects of type 1 are the elements of $\mathcal{Z}(R)$, and hom-arrows are given by commutators: $\text{Comm}(r, s) = \{x \in R \mid rx = xs\}$.

4 Some direct consequences

Underlying orders

For an object A of a quantaloid \mathcal{Q} , denote by $*_A$ the one-object \mathcal{Q} -category whose hom-arrow is the identity 1_A . Given a \mathcal{Q} -category \mathbb{A} , the set $\{a \in \mathbb{A}_0 \mid ta = A\}$ is in bijection with $\text{Cat}(\mathcal{Q})(*_A, \mathbb{A})$: any such object a determines a “constant” functor $\Delta a: *_A \rightarrow \mathbb{A}$; and any such functor $F: *_A \rightarrow \mathbb{A}$ “picks out” an object $a \in \mathbb{A}$. We may thus order the objects of \mathbb{A} by ordering the corresponding constant functors; we will speak of the *underlying order* (\mathbb{A}_0, \leq) of the \mathcal{Q} -category \mathbb{A} . Explicitly, for two objects $a, a' \in \mathbb{A}_0$ we have that $a' \leq a$ if and only if $A := ta = ta'$ and for all $x \in \mathbb{A}_0$, $\mathbb{A}(x, a') \leq \mathbb{A}(x, a)$ in \mathcal{Q} , or equivalently $\mathbb{A}(a', x) \geq \mathbb{A}(a, x)$, or equivalently $1_A \leq \mathbb{A}(a', a)$. Whenever two objects of \mathbb{A} are equivalent in \mathbb{A} ’s underlying order ($a \leq a'$ and $a' \leq a$) then we say that they are *isomorphic objects* (and write $a \cong a'$).

Example 4.1 In the \mathcal{Q} -category $\mathcal{P}Y$, whose objects are \mathcal{Q} -arrows with codomain Y and whose hom-arrows are given by $[-, -]$, the underlying order coincides with the local order in \mathcal{Q} . More precisely, for $f, g: X \rightrightarrows Y$ it is the same to say that $f \leq g$ in $(\mathcal{P}Y)_0$ as to say that $f \leq g$ in $\mathcal{Q}(X, Y)$.

It is immediate that $F \leq G: \mathbb{A} \rightrightarrows \mathbb{B}$ in $\text{Cat}(\mathcal{Q})$ if and only if, for all $a \in \mathbb{A}_0$, $Fa \leq Ga$ in the underlying order of \mathbb{B} . This says that the local structure in the 2-category $\text{Cat}(\mathcal{Q})$ is “pointwise order”. Equivalently we could have written that $F \leq G$ if and only if $1_{ta} \leq \mathbb{B}(Fa, Ga)$ for all $a \in \mathbb{A}_0$, which exhibits the resemblance with the usual notion of “enriched natural transformation”.

Adjoints and equivalences

An arrow $F: \mathbb{A} \rightarrow \mathbb{B}$ is *left adjoint* to an arrow $G: \mathbb{B} \rightarrow \mathbb{A}$ in $\text{Cat}(\mathcal{Q})$ (and G is then *right adjoint* to F), written $F \dashv G$, if $1_{\mathbb{A}} \leq G \circ F$ and $F \circ G \leq 1_{\mathbb{B}}$. Due to the 2-category $\text{Cat}(\mathcal{Q})$ being locally ordered, we needn’t ask any of the usual triangular coherence diagrams. The unicity of adjoints in the quantaloid $\text{Dist}(\mathcal{Q})$ and the locally fully faithful $\text{Cat}(\mathcal{Q}) \rightarrow \text{Dist}(\mathcal{Q})$ allow for the following equivalent expression.

Proposition 4.2 *$F: \mathbb{A} \rightarrow \mathbb{B}$ is left adjoint to $G: \mathbb{B} \rightarrow \mathbb{A}$ in $\text{Cat}(\mathcal{Q})$ if and only if $\mathbb{B}(F-, -) = \mathbb{A}(-, G-): \mathbb{B} \rightarrow \mathbb{A}$ in $\text{Dist}(\mathcal{Q})$.*

Further, $F: \mathbb{A} \rightarrow \mathbb{B}$ is an *equivalence* in $\text{Cat}(\mathcal{Q})$ if there exists a $G: \mathbb{B} \rightarrow \mathbb{A}$ such that $G \circ F \cong 1_{\mathbb{A}}$ and $F \circ G \cong 1_{\mathbb{B}}$ (in which case also G is an equivalence). Again because $\text{Cat}(\mathcal{Q})$ is locally ordered, this is the same as saying that F is both left and right adjoint to some G . Again the functor $\text{Cat}(\mathcal{Q}) \rightarrow \text{Dist}(\mathcal{Q})$ gives equivalent expressions.

Proposition 4.3 *Given functors $F: \mathbb{A} \rightarrow \mathbb{B}$ and $G: \mathbb{B} \rightarrow \mathbb{A}$ constitute an equivalence in $\text{Cat}(\mathcal{Q})$ if and only if $\mathbb{B}(-, F-): \mathbb{A} \rightarrow \mathbb{B}$ and $\mathbb{A}(-, G): \mathbb{B} \rightarrow \mathbb{A}$ constitute an isomorphism in $\text{Dist}(\mathcal{Q})$, if and only if $\mathbb{B}(F-, -): \mathbb{B} \rightarrow \mathbb{A}$ and $\mathbb{A}(-, G-): \mathbb{A} \rightarrow \mathbb{B}$ constitute an isomorphism in $\text{Dist}(\mathcal{Q})$.*

For ordinary categories and functors it is well known that the equivalences are precisely the fully faithful functors which are essentially surjective on objects. This holds for \mathcal{Q} -enriched categories too: say that a functor $F: \mathbb{A} \rightarrow \mathbb{B}$ is *fully faithful* if

$$\forall a, a' \in \mathbb{A}_0 : \mathbb{A}(a', a) = \mathbb{B}(Fa', Fa) \text{ in } \mathcal{Q},$$

and that is *essentially surjective on objects* whenever

$$\forall b \in \mathbb{B}_0, \exists a \in \mathbb{A}_0 : Fa \cong b \text{ in } \mathbb{B}.$$

In fact, F is fully faithful if and only if the unit of the adjunction $\mathbb{B}(-, F-) \dashv \mathbb{B}(F-, -)$ in $\text{Dist}(\mathcal{Q})$ saturates to an equality; and if F is essentially surjective on

objects then necessarily the co-unit of this adjunction saturates to an equality (but a functor $F: \mathbb{A} \rightarrow \mathbb{B}$ for which the co-unit of the induced adjunction is an equality – which is sometimes said to have a “dense image” – is not necessarily essentially surjective on objects).

Proposition 4.4 *An arrow $F: \mathbb{A} \rightarrow \mathbb{B}$ in $\text{Cat}(\mathcal{Q})$ is an equivalence if and only if it is fully faithful and essentially surjective on objects.*

Proof: Suppose that F is an equivalence, with inverse equivalence G . Then, by functoriality of F and G , and since $G \circ F \cong 1_{\mathbb{A}}$, $\mathbb{A}(a', a) \leq \mathbb{B}(Fa', Fa) \leq \mathbb{A}(GFa', GFa) = \mathbb{A}(a', a)$ for all $a, a' \in \mathbb{A}_0$. Further, using $F \circ G \cong 1_{\mathbb{B}}$, it follows that $b \cong FGb$, and $Gb \in \mathbb{A}_0$ as required. Conversely, supposing that F is fully faithful and essentially surjective on objects, choose – using the essential surjectivity of F – for any $b \in \mathbb{B}_0$ one particular object $Gb \in \mathbb{A}_0$ for which $FGb \cong b$. Then the object mapping $\mathbb{B}_0 \rightarrow \mathbb{A}_0: b \mapsto Gb$ is fully faithful itself (and therefore also functorial) due to the fully faithfulness of F : $\mathbb{B}(b', b) = \mathbb{B}(FGb', FGb) = \mathbb{A}(Gb', Gb)$ for all $b, b' \in \mathbb{B}_0$. It is the required inverse equivalence. \square

The following is well known for ordinary categories, and holds for \mathcal{Q} -categories too; it will be useful further on.

Proposition 4.5 *Suppose that $F \dashv G: \mathbb{B} \xrightarrow{\leftarrow} \mathbb{A}$ in $\text{Cat}(\mathcal{Q})$. Then F is fully faithful if and only if $G \circ F \cong 1_{\mathbb{A}}$, and G is fully faithful if and only if $F \circ G \cong 1_{\mathbb{B}}$. If moreover $G \dashv H: \mathbb{A} \xrightarrow{\leftarrow} \mathbb{B}$ in $\text{Cat}(\mathcal{Q})$ then F is fully faithful if and only if H is fully faithful.*

Proof: $F \dashv G$ in $\text{Cat}(\mathcal{Q})$ implies $\mathbb{B}(F-, F-) = \mathbb{A}(-, G \circ F-)$ in $\text{Dist}(\mathcal{Q})$; and F is fully faithful if and only if $\mathbb{B}(F-, F-) = \mathbb{A}(-, -)$ in $\text{Dist}(\mathcal{Q})$. So, obviously, F is fully faithful if and only if $\mathbb{A}(-, G \circ F-) = \mathbb{A}(-, -)$ in $\text{Dist}(\mathcal{Q})$, or equivalently, $G \circ F \cong 1_{\mathbb{A}}$ in $\text{Cat}(\mathcal{Q})$. Likewise for the fully faithfulness of G . Suppose now that $F \dashv G \dashv H$, then $\mathbb{A}(G \circ F-, -) = \mathbb{B}(F-, H-) = \mathbb{B}(-, G \circ H-)$, which implies that $\mathbb{A}(G \circ F-, -) = \mathbb{A}(-, -)$ if and only if $\mathbb{B}(-, G \circ H-) = \mathbb{A}(-, -)$ so the result follows. \square

Left Kan extensions

Given \mathcal{Q} -categories and functors $F: \mathbb{A} \rightarrow \mathbb{B}$ and $G: \mathbb{A} \rightarrow \mathbb{C}$, the *left Kan extension of F along G* is – in so far it exists – a functor $K: \mathbb{C} \rightarrow \mathbb{B}$ such that $K \circ G \geq F$ in a universal way: whenever $K': \mathbb{C} \rightarrow \mathbb{B}$ satisfies $K' \circ G \geq F$, then $K' \geq K$. If the left Kan extension of F along G exists, then it is essentially unique; we denote it $\langle F, G \rangle$. So $\langle F, G \rangle: \mathbb{C} \rightarrow \mathbb{B}$ is the reflection of $F \in \text{Cat}(\mathcal{Q})(\mathbb{A}, \mathbb{B})$ along

$$- \circ G: \text{Cat}(\mathcal{Q})(\mathbb{C}, \mathbb{B}) \rightarrow \text{Cat}(\mathcal{Q})(\mathbb{A}, \mathbb{B}): H \mapsto H \circ G.$$

Left adjoint functors may be characterized in terms of left Kan extensions; this uses the idea of functors that preserve Kan extensions. Suppose that the left Kan

extension $\langle F, G \rangle: \mathbb{C} \rightarrow \mathbb{B}$ exists; then a functor $F': \mathbb{B} \rightarrow \mathbb{B}'$ is said to *preserve* $\langle F, G \rangle$ if $\langle F' \circ F, G \rangle$ exists and is isomorphic to $F' \circ \langle F, G \rangle$. And $\langle F, G \rangle$ is *absolute* if it is preserved by any $F': \mathbb{B} \rightarrow \mathbb{B}'$.

Proposition 4.6 *For a functor $F: \mathbb{A} \rightarrow \mathbb{B}$ between \mathcal{Q} -categories the following are equivalent:*

1. F has a right adjoint;
2. $\langle 1_{\mathbb{A}}, F \rangle$ exists and is absolute;
3. $\langle 1_{\mathbb{A}}, F \rangle$ exists and is preserved by F itself.

In this case, $\langle 1_{\mathbb{A}}, F \rangle$ is the right adjoint of F .

Proof: For (1 \Rightarrow 2), suppose that $F \dashv G$; we'll prove that G is the absolute left Kan extension of $1_{\mathbb{A}}$ along F . The unit of the adjunction already says that $G \circ F \geq 1_{\mathbb{A}}$; and if $K: \mathbb{B} \rightarrow \mathbb{A}$ is another functor such that $K \circ F \geq 1_{\mathbb{A}}$, then necessarily $K = K \circ 1_{\mathbb{B}} \geq K \circ (F \circ G) = (K \circ F) \circ G \geq 1_{\mathbb{A}} \circ G = G$, using now the unit of the adjunction. So indeed $G \cong \langle 1_{\mathbb{A}}, F \rangle$. Let now $F': \mathbb{A} \rightarrow \mathbb{B}'$ be any functor; we claim that $F' \circ G$ is the left Kan extension of $F' \circ 1_{\mathbb{A}}$ along F . Already $(F' \circ G) \circ F = F' \circ (G \circ F) \geq F' \circ 1_{\mathbb{A}}$ is obvious (using the unit of the adjunction); and if $K': \mathbb{B} \rightarrow \mathbb{B}'$ is another functor such that $K' \circ F \geq F' \circ 1_{\mathbb{A}}$, then $K' = K' \circ 1_{\mathbb{B}} \geq K' \circ (F \circ G) = (K' \circ F) \circ G \geq (F' \circ 1_{\mathbb{A}}) \circ G = F' \circ G$. Thus, G is the absolute left Kan extension of $1_{\mathbb{A}}$ along F .

(2 \Rightarrow 3) being trivial, we now prove (3 \Rightarrow 1); it suffices to prove that $F \dashv \langle 1_{\mathbb{A}}, F \rangle$. But the wanted unit $\langle 1_{\mathbb{A}}, F \rangle \circ F \geq 1_{\mathbb{A}}$ is part of the universal property of the left Kan extension; and using the hypothesis that $\langle 1_{\mathbb{A}}, F \rangle$ is preserved by F itself, we have $F \circ \langle 1_{\mathbb{A}}, F \rangle = \langle F, F \rangle$ which is smaller than $1_{\mathbb{B}}$ by the universal property of $\langle F, F \rangle$ (since $1_{\mathbb{B}} \circ F \geq F$). \square

The dual of this result says that a functor $F: \mathbb{A} \rightarrow \mathbb{B}$ has a left adjoint in $\text{Cat}(\mathcal{Q})$ if and only if the *right Kan extension* of $1_{\mathbb{A}}$ along F exists and is absolute, if and only if this right Kan extension exists and is preserved by F . Of course, the definition of *right Kan extension* is the dual of that of left Kan extension: given $F: \mathbb{A} \rightarrow \mathbb{B}$ and $G: \mathbb{A} \rightarrow \mathbb{C}$ in $\text{Cat}(\mathcal{Q})$, the right Kan extension of F along G is a functor $(F, G): \mathbb{C} \rightarrow \mathbb{B}$ such that $(F, G)^{\text{op}}: \mathbb{C}^{\text{op}} \rightarrow \mathbb{B}^{\text{op}}$ is the left Kan extension of F^{op} along G^{op} in $\text{Cat}(\mathcal{Q}^{\text{op}})$. In elementary terms: there is a universal inequality $(F, G) \circ G \leq F$ in $\text{Cat}(\mathcal{Q})$.

After having introduced weighted colimits in a \mathcal{Q} -category, we will discuss *point-wise* left Kan extensions: particular colimits that enjoy the universal property given above.

Skeletal categories

To any order corresponds an antisymmetric order by passing to equivalence classes of elements of the order. For \mathcal{Q} -enriched categories this can be imitated: say that a \mathcal{Q} -category \mathbb{A} is *skeletal* if no two different objects in \mathbb{A} are isomorphic; equivalently this

says that, for any \mathcal{Q} -category \mathbb{C} , $\text{Cat}(\mathcal{Q})(\mathbb{C}, \mathbb{A})$ is an antisymmetric order, i.e. that

$$\text{Cat}(\mathcal{Q})(\mathbb{C}, \mathbb{A}) \longrightarrow \text{Dist}(\mathcal{Q})(\mathbb{C}, \mathbb{A}): F \mapsto \mathbb{A}(-, F-)$$

is injective. Any \mathcal{Q} -category is then equivalent to its “skeletal quotient”.

Proposition 4.7 *For a \mathcal{Q} -category \mathbb{A} , the following data define a skeletal \mathcal{Q} -category \mathbb{A}_{skel} :*

- *objects:* $(\mathbb{A}_{\text{skel}})_0 = \{[a] = \{x \in \mathbb{A}_0 \mid x \cong a\} \mid a \in \mathbb{A}_0\}$, with type function $t[a] = ta$;
- *hom-arrows:* for any $[a], [a'] \in (\mathbb{A}_{\text{skel}})_0$, $\mathbb{A}_{\text{skel}}([a'], [a]) = \mathbb{A}(a', a)$.

The object mapping $[-]: \mathbb{A} \longrightarrow \mathbb{A}_{\text{skel}}: x \mapsto [x]$ determines an equivalence in $\text{Cat}(\mathcal{Q})$.

Proof: The construction of \mathbb{A}_{skel} is well-defined, because:

- as a set the quotient of \mathbb{A}_0 by \cong is well-defined ($\cdot \cong \cdot$ is an equivalence);
- $t[a]$ is well-defined (all elements of the equivalence class $[a]$ necessarily have the same type since they are isomorphic);
- for any $a' \cong b'$ and $a \cong b$ in \mathbb{A} , $\mathbb{A}(b', b) = \mathbb{A}(a', a)$, so $\mathbb{A}_{\text{skel}}([a'], [a])$ is well-defined.

\mathbb{A}_{skel} inherits “composition” and “identities” from \mathbb{A} , so it is a \mathcal{Q} -category. And \mathbb{A}_{skel} is skeletal: if $[a] \cong [a']$ in $(\mathbb{A}_{\text{skel}})_0$ then necessarily $a \cong a'$ in \mathbb{A}_0 , which by definition implies that $[a] = [a']$.

The mapping $\mathbb{A}_0 \longrightarrow (\mathbb{A}_{\text{skel}})_0: x \mapsto [x]$ determines a functor which is obviously fully faithful and essentially surjective on objects, so by 4.4 it is an equivalence in $\text{Cat}(\mathcal{Q})$. \square

Skeletal \mathcal{Q} -categories can be taken as objects of a full sub-2-category of $\text{Cat}(\mathcal{Q})$, respectively a full sub-quantaloid of $\text{Dist}(\mathcal{Q})$; the proposition above then says that $\text{Cat}_{\text{skel}}(\mathcal{Q}) \longrightarrow \text{Cat}(\mathcal{Q})$ is a biequivalence of 2-categories, and $\text{Dist}_{\text{skel}}(\mathcal{Q}) \longrightarrow \text{Dist}(\mathcal{Q})$ is then an equivalence of quantaloids. $\text{Cat}_{\text{skel}}(\mathcal{Q})$ is locally antisymmetrically ordered, so the obvious 2-functor

$$\text{Cat}_{\text{skel}}(\mathcal{Q}) \longrightarrow \text{Dist}_{\text{skel}}(\mathcal{Q}): (F: \mathbb{A} \longrightarrow \mathbb{B}) \mapsto (\mathbb{B}(-, F-): \mathbb{A} \dashv\!\!\dashv\!\!\rightarrow \mathbb{B})$$

is the identity on objects, faithful (but not full), and locally fully faithful.

Example 4.8 The \mathcal{Q} -categories $\mathcal{P}Y$ and $\mathcal{P}^\dagger X$ as defined in 3.9 are skeletal.

Example 4.9 Taking $\mathcal{Q} = \mathbf{2}$, the skeletal $\mathbf{2}$ -categories are precisely the antisymmetric orders, i.e. the partial orders (cf. 3.10).

Example 4.10 The $\text{Rel}(\Omega)$ -category associated to a sheaf on Ω , as in 3.11, is skeletal.

Later on we will encounter important \mathcal{Q} -categories which are always skeletal: the categories $\mathcal{P}\mathbb{A}$ and $\mathcal{P}^\dagger\mathbb{A}$ of (contravariant and covariant) presheaves on a given \mathcal{Q} -category \mathbb{A} , and also \mathbb{A} 's Cauchy completion \mathbb{A}_{cc} . (The reason, ultimately, that these \mathcal{Q} -categories are skeletal, is that the hom-objects of the quantaloid \mathcal{Q} are antisymmetrically ordered.)

5 Weighted (co)limits

Colimits

We consider a functor $F: \mathbb{A} \rightarrow \mathbb{B}$ and a distributor $\Theta: \mathbb{C} \rightarrow \mathbb{A}$ between \mathcal{Q} -categories. Since F determines a distributor $\mathbb{B}(F-, -): \mathbb{B} \rightarrow \mathbb{A}$, and by closedness of the quantaloid $\text{Dist}(\mathcal{Q})$, we can calculate the universal lifting $[\Theta, \mathbb{B}(F-, -)]: \mathbb{B} \rightarrow \mathbb{C}$. A functor $G: \mathbb{C} \rightarrow \mathbb{B}$ is the Θ -weighted colimit of F if it represents the universal lifting: $\mathbb{B}(G-, -) = [\Theta, \mathbb{B}(F-, -)]$. If the Θ -weighted colimit of F exists, then it is necessarily essentially unique. It therefore makes sense to speak of “the” colimit and to denote it by $\text{colim}(\Theta, F)$; its universal property is thus that

$$\mathbb{B}(\text{colim}(\Theta, F)-, -) = [\Theta, \mathbb{B}(F-, -)] \text{ in } \text{Dist}(\mathcal{Q}).$$

The following diagrams picture the situation:

We wish to speak of “those \mathcal{Q} -categories that admit all weighted colimits”, i.e. *cocomplete* \mathcal{Q} -categories. But there is a small problem (the word is well-chosen).

Lemma 5.1 *A cocomplete \mathcal{Q} -category \mathbb{B} has at least as many objects as the base quantaloid \mathcal{Q} .*

Proof: For each $X \in \mathcal{Q}$, consider the empty diagram in \mathbb{B} weighted by the empty distributor with domain $*_X$. Then $\text{colim}(\emptyset, \emptyset): *_X \rightarrow \mathbb{B}$ must exist by cocompleteness of \mathbb{B} ; it “picks out” an object of type X in \mathbb{B} —thus \mathbb{B} must have such an object in the first place. \square

So, by the above, would the base quantaloid have a proper class of objects, then so would all cocomplete \mathcal{Q} -enriched categories. This is a problem in the framework of this text, because we didn’t even bother defining “large” \mathcal{Q} -categories, let

alone develop a theory of \mathcal{Q} -categories that is sensitive to these size-related issues. Therefore, from now on, we are happy to work with a small base quantaloid \mathcal{Q} . The problem of “small” versus “large” then disappears: also “small” \mathcal{Q} -categories can be cocomplete.

Next up is a collection of lemmas that will help us calculate colimits. (There will be some abuse of notation: for a distributor $\Phi: *A \dashv\rightarrow \mathbb{A}$ and a functor $F: \mathbb{A} \rightarrow \mathbb{B}$, $\text{colim}(\Phi, F)$ is in principle a functor from $*A$ to \mathbb{B} . But such a functor simply “picks out” an object of type A in \mathbb{B} . Therefore we will often think of $\text{colim}(\Phi, F)$ just as being that object. Of course, when the domain of the weight has more than one object, then any colimit with that weight is *really* a functor!)

Lemma 5.2 1. For $(\Phi_i: \mathbb{C} \dashv\rightarrow \mathbb{A})_{i \in I}$ and $F: \mathbb{A} \rightarrow \mathbb{B}$, if all colimits involved exist, then $\text{colim}(\bigvee_i \Phi_i, F)$ is the supremum of the $\text{colim}(\Phi_i, F)$ in the order $\text{Cat}(\mathcal{Q})(\mathbb{C}, \mathbb{B})$:

$$\text{colim}\left(\bigvee_i \Phi_i, F\right) \cong \bigvee_i \text{colim}(\Phi_i, F).$$

2. For any $F: \mathbb{A} \rightarrow \mathbb{B}$, $\text{colim}(\mathbb{A}, F)$ (exists and) is isomorphic to F .
3. For $\Phi: \mathbb{D} \dashv\rightarrow \mathbb{C}$, $\Theta: \mathbb{C} \dashv\rightarrow \mathbb{A}$ and $F: \mathbb{A} \rightarrow \mathbb{B}$, suppose that $\text{colim}(\Theta, F)$ exists; then $\text{colim}(\Phi, \text{colim}(\Theta, F))$ exists if and only if $\text{colim}(\Theta \otimes_{\mathbb{C}} \Phi, F)$ exists, in which case they are isomorphic.
4. For $\Theta: \mathbb{C} \dashv\rightarrow \mathbb{A}$ and $F: \mathbb{A} \rightarrow \mathbb{B}$, $\text{colim}(\Theta, F)$ exists if and only if, for all objects $c \in \mathbb{C}_0$, $\text{colim}(\Theta(-, c), F)$ exists; then $\text{colim}(\Theta, F)(c) \cong \text{colim}(\Theta(-, c), F)$.

Proof: (1) By assumption,

$$\begin{aligned} \mathbb{C}\left(\text{colim}\left(\bigvee_i \Phi_i, F\right)-, -\right) &= \left[\bigvee_i \Phi_i, \mathbb{B}(F-, -)\right] \\ &= \bigwedge_i \left[\Phi_i, \mathbb{B}(F-, -)\right] \\ &= \bigwedge_i \mathbb{B}\left(\text{colim}(\Phi_i, F)-, -\right) \end{aligned}$$

from which it follows that $\text{colim}(\bigvee_i \Phi_i, F)$ is the supremum of the $\text{colim}(\Phi_i, F)$ in $\text{Cat}(\mathcal{Q})(\mathbb{C}, \mathbb{B})$.

(2) Trivially, $[\mathbb{A}(-, -), \mathbb{B}(F-, -)] = \mathbb{B}(F-, -)$.

(3) By a simple calculation

$$\left[\Phi, \mathbb{B}\left(\text{colim}(\Theta, F)-, -\right)\right] = \left[\Phi, \left[\Theta, \mathbb{B}(F-, -)\right]\right] = \left[\Theta \otimes_{\mathbb{C}} \Phi, \mathbb{B}(F-, -)\right]$$

so the Φ -weighted colimit of $\text{colim}(\Theta, F)$ and the $\Theta \otimes_{\mathbb{C}} \Phi$ -weighted colimit of F are the same thing.

(4) Necessity is easy: $\text{colim}(\Theta, F): \mathbb{C} \rightarrow \mathbb{B}$ is a functor satisfying, for all $c \in \mathbb{C}_0$ and $b \in \mathbb{B}_0$,

$$\mathbb{B}\left(\text{colim}(\Theta, F)(c), b\right) = \left[\Theta(-, c), \mathbb{B}(F-, b)\right];$$

this literally says that $\text{colim}(\Theta, F)(c)$ is the $\Theta(-, c)$ -weighted colimit of F (which thus exists). As for sufficiency, we prove that the mapping

$$K: \mathbb{C}_0 \rightarrow \mathbb{B}_0: c \mapsto \text{colim}(\Theta(-, c), F)$$

is a functor: $\mathbb{C}(c', c) \leq \mathbb{B}(Kc', Kc)$ because

$$\begin{aligned} \mathbb{B}(Kc', Kc) &= \mathbb{B}(Kc', -) \otimes_{\mathbb{B}} \mathbb{B}(-, Kc) \\ &= \left\{ \mathbb{B}(Kc, -), \mathbb{B}(Kc', -) \right\} \\ &= \left\{ \left[\Phi(-, c), \mathbb{B}(F-, -) \right], \left[\Phi(-, c'), \mathbb{B}(F-, -) \right] \right\} \end{aligned}$$

and, with slight abuse of notation⁴,

$$\begin{aligned} \mathbb{C}(c', c) &\leq \left\{ \left[\Phi(-, c), \mathbb{B}(F-, -) \right], \left[\Phi(-, c'), \mathbb{B}(F-, -) \right] \right\} \\ &\iff \Phi(-, c') \otimes_{*_{tc'}} \mathbb{C}(c', c) \otimes_{*_{tc}} \left[\Phi(-, c), \mathbb{B}(F-, -) \right] \leq \mathbb{B}(F-, -) \end{aligned}$$

which holds because $\Phi(-, c') \otimes_{*_{tc'}} \mathbb{C}(c', c) \leq \Phi(-, c)$ and by the universal property of the “[−, −]”. This functor K has, by construction, the required universal property for it to be the Φ -weighted colimit of F . \square

Lemma 5.3 *For $F \leq G: \mathbb{A} \rightrightarrows \mathbb{B}$ and $\Theta: \mathbb{C} \dashrightarrow \mathbb{A}$, suppose that $\text{colim}(\Theta, F)$ and $\text{colim}(\Theta, G)$ exist; then $\text{colim}(\Theta, F) \leq \text{colim}(\Theta, G)$. In particular, if $F \cong G$ then $\text{colim}(\Theta, F)$ exists if and only if $\text{colim}(\Theta, G)$ exists, in which case they are isomorphic.*

Proof: $[-, -]$ is order-preserving in its second variable, so

$$\mathbb{B}(\text{colim}(\Theta, F)-, -) = \left[\Theta, \mathbb{B}(F-, -) \right] \geq \left[\Theta, \mathbb{B}(G-, -) \right] = \mathbb{B}(\text{colim}(\Theta, G)-, -),$$

hence $\text{colim}(\Theta, F) \leq \text{colim}(\Theta, G)$ as claimed. The second part of the statement is similar. \square

Let us point out two important consequences.

Corollary 5.4 *A \mathcal{Q} -category \mathbb{B} is cocomplete if and only if it admits colimits of the identity functor $1_{\mathbb{B}}: \mathbb{B} \rightarrow \mathbb{B}$ weighted by distributors into \mathbb{B} whose domains are one-object \mathcal{Q} -categories⁵: for every $\phi: *_B \dashrightarrow \mathbb{B}$ in $\text{Dist}(\mathcal{Q})$, there exists an object $b \in \mathbb{B}$, necessarily of type $tb = B$, such that*

$$\mathbb{B}(b, -) = \left[\phi, \mathbb{B} \right] \text{ in } \text{Dist}(\mathcal{Q}).$$

⁴The \mathcal{Q} -arrow $\mathbb{C}(c', c): tc \rightarrow tc'$ is thought of as a one-element distributor $*_{tc} \dashrightarrow *_{tc'}$.

⁵Later we will call those distributors *contravariant presheaves*, so \mathbb{B} is cocomplete if and only if it admits colimits of $1_{\mathbb{B}}$ weighted by contravariant presheaves on \mathbb{B} .

Proof : One direction is trivial. For the other, consider a weight $\Theta: \mathbb{C} \rightarrow \mathbb{A}$ and a functor $F: \mathbb{A} \rightarrow \mathbb{B}$. Then

$$\left[\Theta, \mathbb{B}(F-, -) \right] = \left[\Theta, \left[\mathbb{B}(-, F-), \mathbb{B} \right] \right] = \left[\mathbb{B}(-, F-) \otimes_{\mathbb{A}} \Theta, \mathbb{B}(1_{\mathbb{B}}-, -) \right]$$

so that $\text{colim}(\Theta, F): \mathbb{C} \rightarrow \mathbb{B}$ exists if and only if $\text{colim}(\mathbb{B}(-, F-) \otimes_{\mathbb{A}} \Theta, 1_{\mathbb{B}}): \mathbb{C} \rightarrow \mathbb{B}$ exists. But the latter exists if and only if, for all objects $c \in \mathbb{C}$,

$$\text{colim} \left(\mathbb{B}(-, F-) \otimes_{\mathbb{A}} \Theta(-, c), 1_{\mathbb{B}} \right): *_{tc} \rightarrow \mathbb{B}$$

exists—which they do by hypothesis. \square

Example 5.5 A $\mathbf{2}$ -enriched category \mathbb{A} is an ordered set, and a distributor $\phi: * \rightarrow \mathbb{A}$ is a down-closed subset of \mathbb{A} . Since $[\phi, \mathbb{A}]$ is the up-closed set of lower bounds of ϕ , it is representable if and only if the supremum of ϕ exists in \mathbb{A} . Cocompleteness of \mathbb{A} as $\mathbf{2}$ -category is thus the same thing as cocompleteness of \mathbb{A} as order (since it is equivalent to ask for the suprema of all subsets or only the suprema of down-closed sets).

Corollary 5.6 *Given $(F_i: \mathbb{A} \rightarrow \mathbb{B})_{i \in I}$ in $\text{Cat}(\mathcal{Q})$, if the $\bigvee_i \mathbb{B}(-, F_i-)$ -weighted colimit of $1_{\mathbb{B}}$ exists, then it is their supremum in the order $\text{Cat}(\mathcal{Q})(\mathbb{A}, \mathbb{B})$:*

$$\bigvee_i F_i \cong \text{colim} \left(\bigvee_i \mathbb{B}(-, F_i-), 1_{\mathbb{B}} \right).$$

Proof : The colimit, supposed to exist, satisfies

$$\begin{aligned} \mathbb{B} \left(\text{colim} \left(\bigvee_i \mathbb{B}(-, F_i-), 1_{\mathbb{B}} \right) -, - \right) &= \left[\bigvee_i \mathbb{B}(-, F_i-), \mathbb{B} \right] \\ &= \bigwedge_i \left[\mathbb{B}(-, F_i-), \mathbb{B} \right] \\ &= \bigwedge_i \mathbb{B}(F_i-, -). \end{aligned}$$

It follows straightforwardly that $\text{colim}(\bigvee_i \mathbb{B}(-, F_i-), 1_{\mathbb{B}})$ is the supremum of the F_i . \square

This corollary thus says that, if there is a functor $F: \mathbb{A} \rightarrow \mathbb{B}$ such that $\mathbb{B}(F-, -) = \bigwedge_i \mathbb{B}(F_i-, -)$ for given $(F_i: \mathbb{A} \rightarrow \mathbb{B})_{i \in I}$, then F is the supremum of the F_i . In particular, for an object $a \in \mathbb{A}$ it follows that Fa is the supremum of the $F_i a$ in the underlying order (\mathbb{B}, \leq) .

Example 5.7 Concerning the result in 5.6, it is *not* true that each supremum in the order $\text{Cat}(\mathcal{Q})(\mathbb{A}, \mathbb{B})$ is necessarily a weighted colimit in \mathbb{B} . Consider the orders

then the order morphisms $f(0) = a$, $f(1) = c$ and $g(0) = b$, $g(1) = c$ admit the supremum $h(0) = h(1) = c$, but clearly $h(0)$ is not the supremum of $f(0)$ and $g(0)$. This implies that h is not the weighted colimit determined by f and g as in 5.6.

Limits

A *limit* in a \mathcal{Q} -category \mathbb{A} is a colimit in the opposite category of \mathbb{A} . This simple definition hides the difficulty that \mathbb{A} is a \mathcal{Q} -category but \mathbb{A}^{op} is a \mathcal{Q}^{op} -category. Let us therefore make the definition of limit in \mathbb{A} elementary in terms of \mathcal{Q} -enriched structures: for a distributor $\Phi: \mathbb{B} \multimap \mathbb{C}$ in $\text{Dist}(\mathcal{Q})$ and a functor $F: \mathbb{B} \rightarrow \mathbb{A}$ in $\text{Cat}(\mathcal{Q})$, the Φ -weighted limit of F is – whenever it exists – a functor $\lim(\Phi, F): \mathbb{C} \rightarrow \mathbb{A}$ in $\text{Cat}(\mathcal{Q})$ such that

$$\mathbb{A}(-, \lim(\Phi, F) -) = \left\{ \Phi, \mathbb{A}(-, F-) \right\} \text{ in } \text{Dist}(\mathcal{Q}).$$

These diagrams picture the situation:

A \mathcal{Q} -category \mathbb{A} is *complete* when the \mathcal{Q}^{op} -category \mathbb{A}^{op} is cocomplete; by 5.4 we know that this is so precisely when for all $\phi: *_A \multimap \mathbb{A}^{\text{op}}$ in $\text{Dist}(\mathcal{Q}^{\text{op}})$, the ϕ -weighted colimit of $1_{\mathbb{A}^{\text{op}}}$ exists in $\text{Cat}(\mathcal{Q}^{\text{op}})$; in terms of \mathcal{Q} -enriched structures, this occurs precisely when for every⁶ $\phi: \mathbb{A} \multimap *_A$ in $\text{Dist}(\mathcal{Q})$, there is an object $a \in \mathbb{A}$, necessarily of type $ta = A$, such that

$$\mathbb{A}(-, a) = \left\{ \phi, \mathbb{A} \right\} \text{ in } \text{Dist}(\mathcal{Q}).$$

Proposition 5.8 *For any \mathcal{Q} -category \mathbb{A} and any $\phi: \mathbb{A} \multimap *_A$ in $\text{Dist}(\mathcal{Q})$, $\lim(\phi, 1_{\mathbb{A}})$ exists if and only if $\text{colim}(\{\phi, \mathbb{A}\}, 1_{\mathbb{A}})$ exists, in which case they are isomorphic.*

Proof: First suppose that $a = \lim(\phi, 1_{\mathbb{A}})$ exists: $\mathbb{A}(-, a) = \{\phi, \mathbb{A}\}$. But then, using that $\mathbb{A}(-, a) \dashv \mathbb{A}(a, -)$ in $\text{Dist}(\mathcal{Q})$, $\mathbb{A}(a, -) = [\mathbb{A}(-, a), \mathbb{A}] = [\{\phi, \mathbb{A}\}, \mathbb{A}]$, which says that a is the $\{\phi, \mathbb{A}\}$ -weighted colimit of $1_{\mathbb{A}}$.

⁶Later we will call such a distributor a *covariant presheaf* on \mathbb{A} .

Conversely, to say that $a = \text{colim}(\{\phi, \mathbb{A}\}, 1_{\mathbb{A}})$ exists, means that $\mathbb{A}(a, -) = [\{\phi, \mathbb{A}\}, \mathbb{A}]$. Again using the adjunction $\mathbb{A}(-, a) \dashv \mathbb{A}(a, -)$, and by calculation with $[-, -]$ and $\{-, -\}$ in $\text{Dist}(\mathcal{Q})$ it follows that $\mathbb{A}(-, a) = \{[\{\phi, \mathbb{A}\}, \mathbb{A}], \mathbb{A}\} = \{\phi, \mathbb{A}\}$, so that indeed a is the ϕ -weighted colimit of $1_{\mathbb{A}}$. \square

This proposition is valid for categories enriched in any quantaloid \mathcal{Q} , hence also for \mathcal{Q}^{op} -categories; translating the result in 5.8 for \mathcal{Q}^{op} -categories in terms of \mathcal{Q} -categories, we obtain its dual: for any $\psi: *_A \dashv\!\!\dashv \mathbb{A}$ in $\text{Dist}(\mathcal{Q})$, $\text{colim}(\psi, 1_{\mathbb{A}})$ exists if and only if $\text{lim}([\psi, \mathbb{A}], 1_{\mathbb{A}})$ exists, in which case they are isomorphic.

Example 5.9 Applied to **2**-enriched categories, i.e. ordered sets, 5.8 says that the infimum of an up-closed subset equals the supremum of the down-set of its lower bounds (and dually, the supremum of a down-closed subset equals the infimum of the up-closed set of its upper bounds).

The following is then an immediate consequence of 5.4 and 5.8.

Proposition 5.10 *A \mathcal{Q} -category is complete if and only if it is cocomplete.*

This does not mean that “the theory of complete \mathcal{Q} -categories” is *the same* as “the theory of cocomplete \mathcal{Q} -categories” (although it is its dual): even though the objects are the same, the appropriate morphisms are not. For example, the free cocompletion of a \mathcal{Q} -category is different from its free completion (see further).

Absolute (co)limits and (co)continuous functors

Given a distributor $\Theta: \mathbb{A} \dashv\!\!\dashv \mathbb{B}$ and a functor $F: \mathbb{B} \rightarrow \mathbb{C}$ between \mathcal{Q} -categories for which $\text{colim}(\Theta, F): \mathbb{C} \rightarrow \mathbb{B}$ exists, a functor $F': \mathbb{B} \rightarrow \mathbb{B}'$ is said to *preserve* this colimit if $\text{colim}(\Theta, F' \circ F)$ exists and is isomorphic to $F' \circ \text{colim}(\Theta, F)$. The functor F' is *cocontinuous* if it preserves all colimits that exist in \mathbb{B} . And $\text{colim}(\Theta, F)$ is *absolute* if it is preserved by any functor $F': \mathbb{B} \rightarrow \mathbb{B}'$.

Continuous functors and *absolute limits* are defined dually. For all of the following results we don't bother explicitly writing the dual statements, even though we may use them further on.

Proposition 5.11 *If $\Theta: \mathbb{C} \dashv\!\!\dashv \mathbb{A}$ is a left adjoint in $\text{Dist}(\mathcal{Q})$, then any colimit with weight Θ is absolute⁷.*

Proof: If $\Theta \dashv \Psi$ in $\text{Dist}(\mathcal{Q})$ and $\text{colim}(\Theta, F)$ exists, then necessarily

$$\mathbb{B}\left(\text{colim}(\Theta, F)-, -\right) = \left[\Theta, \mathbb{B}(F-, -)\right] = \Psi \otimes_{\mathbb{A}} \mathbb{B}(F-, -).$$

⁷A converse can be proved too: if any Θ -weighted colimit is absolute, then Θ is left adjoint [Street, 1983b].

From this it is obvious that, for any $F': \mathbb{B} \rightarrow \mathbb{B}'$,

$$\begin{aligned}
\mathbb{B}(F' \circ \operatorname{colim}(\Theta, F) -, -) &= \mathbb{B}(\operatorname{colim}(\Theta, F) -, -) \otimes_{\mathbb{B}} \mathbb{B}'(F' -, -) \\
&= \Psi \otimes_{\mathbb{A}} \mathbb{B}(F -, -) \otimes_{\mathbb{B}} \mathbb{B}'(F' -, -) \\
&= \Psi \otimes_{\mathbb{A}} \mathbb{B}(F' \circ F -, -) \\
&= [\Theta, \mathbb{B}(F' \circ F -, -)]
\end{aligned}$$

so $\operatorname{colim}(\Theta, F' \circ F)$ exists and is isomorphic to $F' \circ \operatorname{colim}(\Theta, F)$. \square

Proposition 5.12 *If $F': \mathbb{B} \rightarrow \mathbb{B}'$ is a left adjoint in $\operatorname{Cat}(\mathcal{Q})$, then it is cocontinuous⁸.*

Proof: Suppose that $F' \dashv G$ in $\operatorname{Cat}(\mathcal{Q})$ —i.e. $\mathbb{B}'(F' -, -) \dashv \mathbb{B}(G -, -)$ in $\operatorname{Dist}(\mathcal{Q})$. For any colimit

$$\begin{array}{ccccc}
\mathbb{A} & \xrightarrow{F} & \mathbb{B} & \xrightarrow{F'} & \mathbb{B}' \\
\uparrow \Theta & & \nearrow \operatorname{colim}(\Theta, F) & & \\
\mathbb{C} & & & &
\end{array}$$

we can then calculate

$$\begin{aligned}
\mathbb{B}'(F' \circ \operatorname{colim}(\Theta, F) -, -) &= \mathbb{B}'(\operatorname{colim}(\Theta, F) -, -) \otimes_{\mathbb{B}} \mathbb{B}'(F' -, -) \\
&= [\Theta, \mathbb{B}(F -, -)] \otimes_{\mathbb{B}} \mathbb{B}'(F' -, -) \\
&= \left\{ \mathbb{B}(G -, -), [\Theta, \mathbb{B}(F -, -)] \right\} \\
&= [\Theta, \left\{ \mathbb{B}(G -, -), \mathbb{B}(F -, -) \right\}] \\
&= [\Theta, \mathbb{B}(F -, -) \otimes_{\mathbb{B}} \mathbb{B}'(F' -, -)] \\
&= [\Theta, \mathbb{B}'(F' \circ F -, -)]
\end{aligned}$$

which shows that $\operatorname{colim}(\Theta, F' \circ F)$ exists and equals $F' \circ \operatorname{colim}(\Theta, F)$. \square

Corollary 5.13 *Consider a fully faithful right adjoint $G: \mathbb{B} \rightarrow \mathbb{A}$ in $\operatorname{Cat}(\mathcal{Q})$; if \mathbb{B} is cocomplete, then so is \mathbb{A} .*

⁸If \mathbb{B} is cocomplete, then also the converse holds—see 6.8.

Proof: Let us write $F: \mathbb{A} \rightarrow \mathbb{B}$ for G 's left adjoint; now consider any colimit diagram

$$\begin{array}{ccccc}
 & & & & F \\
 & & & \swarrow & \perp \\
 \mathbb{D} & \xrightarrow{H} & \mathbb{A} & \xrightarrow{G} & \mathbb{B} \\
 \uparrow \Phi & & \nearrow & & \\
 \mathbb{C} & & & & \\
 & & \text{colim}(\Phi, G \circ H) & &
 \end{array}$$

Then by cocontinuity of F we have $F \circ \text{colim}(\Phi, G \circ H) \cong \text{colim}(\Phi, F \circ G \circ H)$ (thus in particular the existence of the right hand side, the dotted arrow in the diagram), and by fully faithfulness of G (see 4.5), $\text{colim}(\Phi, F \circ G \circ H) \cong \text{colim}(\Phi, H)$. \square

The following two corollaries are now immediate.

Corollary 5.14 *Consider a string of three adjoints in $\text{Cat}(\mathcal{Q})$,*

$$\begin{array}{ccc}
 & F & \\
 & \perp & \\
 \mathbb{A} & \xleftarrow{G} & \mathbb{B} \\
 & \perp & \\
 & H &
 \end{array}
 ,$$

with F fully faithful. If \mathbb{B} is cocomplete, then so is \mathbb{A} .

Corollary 5.15 *If $F: \mathbb{A} \rightarrow \mathbb{B}$ is an equivalence in $\text{Cat}(\mathcal{Q})$, then both F and its inverse equivalence are cocontinuous, and \mathbb{A} is cocomplete if and only if \mathbb{B} is.*

6 Presheaves

Contravariant presheaves

Principally the ‘‘contravariant presheaves on a \mathcal{Q} -category \mathbb{A} ’’ should be the objects of a \mathcal{Q} -category $\mathcal{P}\mathbb{A}$ which ‘‘classifies’’ distributors into \mathbb{A} :

$$\text{for every } \mathcal{Q}\text{-category } \mathbb{C}, \text{Dist}(\mathcal{Q})(\mathbb{C}, \mathbb{A}) \simeq \text{Cat}(\mathcal{Q})(\mathbb{C}, \mathcal{P}\mathbb{A}). \quad (11)$$

(Here we ask *a priori* for an equivalence of orders, but it will prove to be an isomorphism of sup-lattices.) Putting $\mathbb{C} = *_C$ in the above equivalence dictates that a *contravariant presheaf of type $C \in \mathcal{Q}$ on \mathbb{A}* is a distributor $*_C \rightarrow \mathbb{A}$.

In what follows we will systematically use small greek letters – instead of capital ones – to denote such contravariant presheaves; the elements of such a $\phi: *_C \rightarrow \mathbb{A}$ will be written as $\phi(a): C \rightarrow ta$ (instead of $\phi(a, *)$, thus stressing the fact that the action of $*_C$ on ϕ is trivial).

The precise sense in which a distributor $\phi: *_C \rightarrow \mathbb{A}$ is *contravariant*, is the following: the action of \mathbb{A} on ϕ can be written as $\mathbb{A}(a', a) \leq \{\phi(a), \phi(a')\}$ (for all

$a, a' \in \mathbb{A}_0$). A contravariant presheaf on \mathbb{A} may thus be thought of as a “functor on \mathbb{A}^{op} with values in \mathcal{Q} ” sending a to $\phi(a)$. To make this precise: indeed, $a \mapsto \phi(a)$ is a functor between \mathbb{A}^{op} and $(\mathcal{P}^\dagger C)^{\text{op}}$ (see 3.9) in $\text{Cat}(\mathcal{Q}^{\text{op}})$, or equivalently a functor between \mathbb{A} and $\mathcal{P}^\dagger C$ in $\text{Cat}(\mathcal{Q})^{\text{co}}$ (by the duality in 3.8).

Since we agreed to work over a *small* base quantaloid \mathcal{Q} , the collection of contravariant presheaves on a \mathcal{Q} -category \mathbb{A} forms a \mathcal{Q} -typed set⁹. We now need to enrich this set in \mathcal{Q} in such a way that the classifying property in (11) holds.

Proposition 6.1 *For any \mathcal{Q} -category \mathbb{A} , the following defines the \mathcal{Q} -category $\mathcal{P}\mathbb{A}$ of contravariant presheaves on \mathbb{A} :*

- *objects:* $(\mathcal{P}\mathbb{A})_0 = \{\phi: *_C \dashv\!\!\dashv \mathbb{A} \text{ in } \text{Dist}(\mathcal{Q}) \mid C \in \mathcal{Q}\}$ with types $t(\phi: *_C \dashv\!\!\dashv \mathbb{A}) = C$;
- *hom-arrows:* for $\phi: *_C \dashv\!\!\dashv \mathbb{A}$ and $\psi: *_C' \dashv\!\!\dashv \mathbb{A}$ put $\mathcal{P}\mathbb{A}(\psi, \phi): C \rightarrow C'$ to be the single element of the distributor $[\psi, \phi]: *_C \dashv\!\!\dashv *_C'$.

This \mathcal{Q} -category is skeletal, and it satisfies the equivalence in (11) as follows:

- *for a distributor $\Phi: \mathbb{C} \dashv\!\!\dashv \mathbb{A}$ the corresponding functor $F_\Phi: \mathbb{C} \rightarrow \mathcal{P}\mathbb{A}$ maps $c \in \mathbb{C}_0$ onto $\Phi(-, c): tc \dashv\!\!\dashv \mathbb{A}$;*
- *and for a functor $F: \mathbb{C} \rightarrow \mathcal{P}\mathbb{A}$ the corresponding distributor $\Phi_F: \mathbb{C} \dashv\!\!\dashv \mathbb{A}$ has elements, for $(c, a) \in \mathbb{C}_0 \times \mathbb{A}_0$, $\Phi_F(a, c) = F(c)(a)$.*

Proof: With the properties of “ $[-, -]$ ” in $\text{Dist}(\mathcal{Q})$ it is easily verified that $\mathcal{P}\mathbb{A}$ is a \mathcal{Q} -category. For $\phi, \psi \in \mathcal{P}\mathbb{A}$, observe that $\phi \leq \psi$ in $(\mathcal{P}\mathbb{A})_0$ if and only if $t\phi = t\psi =: C$ and $(1_C) \leq \mathcal{P}\mathbb{A}(\phi, \psi)$, that is to say, $\phi, \psi: *_C \dashv\!\!\dashv \mathbb{A}$ and $1_C \leq [\phi, \psi]$ in $\text{Dist}(\mathcal{Q})$, thus precisely when $\phi \leq \psi: *_C \dashv\!\!\dashv \mathbb{A}$. This shows that the underlying order on the objects of $\mathcal{P}\mathbb{A}$ (which are certain distributors) coincides with their order as arrows in $\text{Dist}(\mathcal{Q})$ —so it is antisymmetric, i.e. $\mathcal{P}\mathbb{A}$ is a skeletal \mathcal{Q} -category. As for the equivalence of orders in (11), it is easily seen that the mappings $F \mapsto \Phi_F$ and $\Phi \mapsto F_\Phi$ as in the statement of the proposition define a bijection:

- for any $c \in \mathbb{C}_0$, $F_{\Phi_F}(c) = \Phi_F(-, c) = F(c)$, so $F_{\Phi_F} = F$,
- for any $(c, a) \in \mathbb{C}_0 \times \mathbb{A}_0$, $\Phi_{F_\Phi}(a, c) = F_\Phi(c)(a) = \Phi(a, c)$, so $\Phi_{F_\Phi} = \Phi$.

This bijection preserves order in both directions:

$$\begin{aligned}
& \Phi \leq \Psi \text{ in } \text{Dist}(\mathbb{C}, \mathbb{A}) \\
& \iff \forall (c, a) \in \mathbb{C}_0 \times \mathbb{A}_0 : \Phi(a, c) \leq \Psi(a, c) \text{ in } \mathcal{Q}(tc, ta) \\
& \iff \forall c \in \mathbb{C}_0 : F_\Phi(c) \leq F_\Psi(c) \text{ in } ((\mathcal{P}\mathbb{A})_0, \leq) \\
& \iff F_\Phi \leq F_\Psi \text{ in } \text{Cat}(\mathcal{Q})(\mathbb{C}, \mathcal{P}\mathbb{A})
\end{aligned}$$

⁹Would the objects of the base category \mathcal{Q} form a class, then the collection of contravariant presheaves on \mathbb{A} would be large! The reason – ultimately – is that $\mathcal{P}\mathbb{A}$ is a cocomplete category—see 5.1 and 6.4.

and likewise

$$\begin{aligned}
& F \leq G \text{ in } \text{Cat}(\mathcal{Q})(\mathbb{C}, \mathcal{P}\mathbb{A}) \\
& \iff \forall c \in \mathbb{C}_0 : F(c) \leq G(c) \text{ in } ((\mathcal{P}\mathbb{A})_0, \leq) \\
& \iff \forall (c, a) \in \mathbb{C}_0 \times \mathbb{A}_0 : \Phi_F(a, c) \leq \Phi_G(a, c) \text{ in } \mathcal{Q}(tc, ta) \\
& \iff \Phi_F \leq \Phi_G \text{ in } \text{Dist}(\mathbb{C}, \mathbb{A}).
\end{aligned}$$

□

Example 6.2 For a \mathcal{Q} -object Y , the \mathcal{Q} -category of contravariant presheaves on $*_Y$ is denoted $\mathcal{P}Y$ instead of $\mathcal{P}(*_Y)$ —see also 3.9.

Very often there will be an abuse of notation: for $\phi: *_C \dashrightarrow \mathbb{A}$ and $\psi: *_C \dashrightarrow \mathbb{A}$ there is a *distributor* $[\psi, \phi]: *_C \dashrightarrow *_C$ with precisely one element (because it goes between one-object categories); therefore we defined $\mathcal{P}\mathbb{A}(\psi, \phi)$ to be *the single element* of this distributor, for we want $\mathcal{P}\mathbb{A}(\psi, \phi)$ to be a \mathcal{Q} -arrow. But more often than not we will simply write $\mathcal{P}\mathbb{A}(\psi, \phi) = [\psi, \phi]$, thus identifying a quantaloid \mathcal{Q} with the full subcategory of $\text{Dist}(\mathcal{Q})$ determined by the one-object \mathcal{Q} -categories whose hom-arrows are identities (see also (9) and the appendix).

The equivalence of orders in (11) has a nice side-effect: $\text{Cat}(\mathcal{Q})(\mathbb{C}, \mathcal{P}\mathbb{A})$ is – by skeletality of $\mathcal{P}\mathbb{A}$ – an antisymmetric order which is order-isomorphic to the sup-lattice $\text{Dist}(\mathcal{Q})(\mathbb{C}, \mathbb{A})$, thus it is a sup-lattice too. In particular are $F \mapsto \Phi_F$ and $\Phi \mapsto F_\Phi$ sup-morphisms.

To the identity distributor $\mathbb{A}: \mathbb{A} \dashrightarrow \mathbb{A}$ corresponds, under the equivalence in (11), the functor

$$Y_{\mathbb{A}}: \mathbb{A} \longrightarrow \mathcal{P}\mathbb{A} : a \mapsto (\mathbb{A}(-, a): *_a \dashrightarrow \mathbb{A})$$

which is, of course, the *Yoneda embedding* for \mathbb{A} . The presheaf $\mathbb{A}(-, a): *_a \dashrightarrow \mathbb{A}$ is said to be *represented* by $a \in \mathbb{A}_0$. We can now prove the “Yoneda lemma” for presheaves on a \mathcal{Q} -enriched category.

Proposition 6.3 *For any \mathcal{Q} -category \mathbb{A} , any object $a \in \mathbb{A}_0$ and any $\phi: *_C \dashrightarrow \mathbb{A}$ in $\text{Dist}(\mathcal{Q})$, $\mathcal{P}\mathbb{A}(Y_{\mathbb{A}}a, \phi) = \phi(a)$. As a consequence, the Yoneda embedding $Y_{\mathbb{A}}: \mathbb{A} \longrightarrow \mathcal{P}\mathbb{A}$ is fully faithful.*

Proof: Using that $\mathbb{A}(-, a) \dashv \mathbb{A}(a, -)$ in $\text{Dist}(\mathcal{Q})$, we have by definition of $\mathcal{P}\mathbb{A}(-, -)$ that $\mathcal{P}\mathbb{A}(Y_{\mathbb{A}}a, \phi) = [\mathbb{A}(-, a), \phi] = \mathbb{A}(a, -) \otimes_{\mathbb{A}} \phi = \phi(a)$. □

An – almost – immediate but non the less important consequence of 6.1 is the following.

Proposition 6.4 *The category $\mathcal{P}\mathbb{B}$ of contravariant presheaves on a \mathcal{Q} -category \mathbb{B} is cocomplete.*

Proof: Given a distributor $\Theta: \mathbb{C} \dashrightarrow \mathbb{A}$ and a functor $F: \mathbb{A} \longrightarrow \mathcal{P}\mathbb{B}$, to F corresponds a unique distributor $\Phi_F: \mathbb{A} \dashrightarrow \mathbb{B}$ and, in turn, to $\Phi_F \otimes_{\mathbb{A}} \Theta: \mathbb{C} \dashrightarrow \mathbb{B}$ corresponds a

unique functor $F_{\Phi_F \otimes_{\mathbb{A}} \Theta}: \mathbb{C} \rightarrow \mathcal{P}\mathbb{B}$. We claim that this latter functor is the colimit of F weighted by Θ : for any $c \in \mathbb{C}$ and $\beta \in \mathcal{P}\mathbb{B}$ we should verify that

$$\mathcal{P}\mathbb{B}\left(F_{\Phi_F \otimes_{\mathbb{A}} \Theta}(c), \beta\right) = \left[\Phi(-, c), \mathcal{P}\mathbb{B}(F-, \beta)\right].$$

The left hand side equals $[\Phi(-, c), [F-, \beta]]$ and the right hand side equals

$$\left[(\Phi_F \otimes_{\mathbb{A}} \Theta)(-, c), \beta\right] = \left[\Phi_F \otimes_{\mathbb{A}} \Theta(-, c), \beta\right] = \left[\Theta(-, c), [\Phi_F, \beta]\right].$$

Since $[F-, \beta] = [\Phi_F, \beta]$, the required universality holds. \square

Corollary 6.5 *For any $\phi: *_C \rightarrow \mathbb{A}$, the ϕ -weighted colimit of $Y_{\mathbb{A}}: \mathbb{A} \rightarrow \mathcal{P}\mathbb{A}$ (exists and) is ϕ itself.*

In other words, every contravariant presheaf on a \mathcal{Q} -category \mathbb{A} is canonically the colimit of representable presheaves: $\text{colim}(\phi, Y_{\mathbb{A}}) = \phi$ (and we may write an equality instead of merely an isomorphism, for $\mathcal{P}\mathbb{A}$ is skeletal).

Here is another result that should sound familiar.

Proposition 6.6 *The Yoneda embedding $Y_{\mathbb{A}}: \mathbb{A} \rightarrow \mathcal{P}\mathbb{A}$ is continuous.*

Proof: Consider a weighted limit (which happens to exist) in \mathbb{A} , like so:

$$\begin{array}{ccccc} & & \mathbb{C} & & \\ & & \uparrow & \text{lim}(\Phi, F) & \\ & & \Phi \circ & \swarrow & \\ \mathbb{B} & \xrightarrow{F} & \mathbb{A} & \xrightarrow{Y_{\mathbb{A}}} & \mathcal{P}\mathbb{A} \end{array}$$

Then, for any $c \in \mathbb{C}_0$,

$$\left(Y_{\mathbb{A}} \circ \text{lim}(\Phi, F)\right)(c) = \mathbb{A}\left(-, \text{lim}(\Phi, F)(c)\right) = \left\{\Phi(c, -), \mathbb{A}(-, F-)\right\}$$

and therefore

$$\begin{aligned} \mathcal{P}\mathbb{A}(-, Y_{\mathbb{A}} \circ \text{lim}(\Phi, F)-) &= \left[-, \left\{\Phi, \mathbb{A}(-, F-)\right\}\right] \\ &= \left\{\Phi, \left[-, \mathbb{A}(-, F-)\right]\right\} \\ &= \left\{\Phi, \mathcal{P}\mathbb{A}(-, Y_{\mathbb{A}} \circ F-)\right\} \end{aligned}$$

so $Y_{\mathbb{A}} \circ \text{lim}(\Phi, F)$ is $\text{lim}(\Phi, Y_{\mathbb{A}} \circ F)$. \square

When $Y_{\mathbb{A}}: \mathbb{A} \rightarrow \mathcal{P}\mathbb{A}$ is a right adjoint, then \mathbb{A} is cocomplete (combine 5.13 with 6.3 and 6.4). Also the converse can be shown; actually, $\mathcal{P}\mathbb{A}$ is the free cocompletion of \mathbb{A} in $\text{Cat}(\mathcal{Q})$. To make this precise in an elegant way, it is useful to treat pointwise left Kan extensions first.

Pointwise left Kan extensions

If for $F: \mathbb{B} \rightarrow \mathbb{A}$ and $G: \mathbb{B} \rightarrow \mathbb{C}$ in $\text{Cat}(\mathcal{Q})$ the $\mathbb{C}(G-, -)$ -weighted colimit of F exist, then it is the left Kan extension of F along G ; so $\langle F, G \rangle \cong \text{colim}(\mathbb{C}(G-, -), F)$ whenever the right hand side exists. By lemma 5.2 we know that in this case the action of $\langle F, G \rangle: \mathbb{C} \rightarrow \mathbb{B}$ on objects is given by the colimit formula $\langle F, G \rangle(c) \cong \text{colim}(\mathbb{C}(G-, c), F)$. Such a colimit weighted by the right adjoint distributor determined by some functor is therefore said to be a *pointwise left Kan extension*. (Note that, for a pointwise left Kan extension, the two notions of absoluteness, one relevant for Kan extensions and the other relevant for colimits, coincide.)

A \mathcal{Q} -category is said to *admit all pointwise left Kan extensions* when it admits all colimits of this special kind. A cocomplete \mathcal{Q} -category then certainly admits all pointwise left Kan extensions. (For a cocomplete \mathbb{B} , any functor $G: \mathbb{A} \rightarrow \mathbb{C}$ thus determines an adjunction

$$\langle -, G \rangle \dashv (- \circ G): \text{Cat}(\mathcal{Q})(\mathbb{C}, \mathbb{B}) \xleftrightarrow{\quad} \text{Cat}(\mathcal{Q})(\mathbb{A}, \mathbb{B}).$$

This has been called the “meta-adjointness” associated to the concept of Kan extension.) But it is also true that a \mathcal{Q} -category admitting all pointwise Kan extensions, is cocomplete! This follows from 5.4 in combination with 6.9 below; note that the Yoneda embedding plays a crucial rôle.

Proposition 6.7 *Suppose that for $F: \mathbb{B} \rightarrow \mathbb{A}$ and $G: \mathbb{B} \rightarrow \mathbb{C}$ in $\text{Cat}(\mathcal{Q})$ the pointwise left Kan extension of F along G exists. If G is fully faithful, then $\langle F, G \rangle \circ G \cong F$.*

Proof: It is easily seen that, $\langle F, G \rangle$ being a pointwise left Kan extension,

$$\begin{aligned} \langle F, G \rangle \circ G &\cong F \\ \iff \mathbb{B}(\langle F, G \rangle \circ G-, -) &= \mathbb{B}(F-, -) \\ \iff \mathbb{C}(G-, -) \otimes_{\mathbb{C}} \mathbb{B}(\langle F, G \rangle-, -) &= \mathbb{B}(F-, -) \\ \iff \mathbb{C}(G-, -) \otimes_{\mathbb{C}} \left[\mathbb{C}(G-, -), \mathbb{B}(F-, -) \right] &= \mathbb{B}(F-, -) \\ \iff \mathbb{C}(G-, -) \otimes_{\mathbb{C}} \mathbb{C}(-, G-) \otimes_{\mathbb{A}} \mathbb{B}(F-, -) &= \mathbb{B}(F-, -) \\ \iff \mathbb{C}(G-, G-) \otimes_{\mathbb{A}} \mathbb{B}(F-, -) &= \mathbb{B}(F-, -) \end{aligned}$$

so if G is fully faithful, i.e. $\mathbb{C}(G-, G-) = \mathbb{A}$, then the above holds. \square

Proposition 6.8 *Let \mathbb{A} be a cocomplete \mathcal{Q} -category; then the cocontinuous functors with domain \mathbb{A} coincide with the left adjoints.*

Proof: One direction is a consequence of 5.12. To prove the other, let $F: \mathbb{A} \rightarrow \mathbb{B}$ be a cocontinuous functor. By cocompleteness of \mathbb{A} , $\langle 1_{\mathbb{A}}, F \rangle$ not only exists but is even pointwise, i.e. it is a colimit, so it must be preserved by F . By 4.6 we conclude that F is a left adjoint. \square

Proposition 6.9 *A functor $F: \mathbb{A} \rightarrow \mathbb{B}$ has a pointwise left Kan extension along $Y_{\mathbb{A}}: \mathbb{A} \rightarrow \mathcal{P}\mathbb{A}$ if and only if, for every $\phi \in \mathcal{P}\mathbb{A}$, the ϕ -weighted colimit of F exists. In this case, $\langle F, Y_{\mathbb{A}} \rangle: \mathcal{P}\mathbb{A} \rightarrow \mathbb{B}$ is left adjoint to $\langle Y_{\mathbb{A}}, F \rangle: \mathbb{B} \rightarrow \mathcal{P}\mathbb{A}$, and $\langle F, Y_{\mathbb{A}} \rangle \circ Y_{\mathbb{A}} \cong F$. Actually, $\langle F, Y_{\mathbb{A}} \rangle$ is then the essentially unique cocontinuous factorization of F through $Y_{\mathbb{A}}$.*

Proof: If by hypothesis, $\langle F, Y_{\mathbb{A}} \rangle = \text{colim}(\mathcal{P}\mathbb{A}(Y_{\mathbb{A}}-, -), F)$ exists, then $\langle F, Y_{\mathbb{A}} \rangle(\phi) = \text{colim}(\mathcal{P}\mathbb{A}(Y_{\mathbb{A}}-, \phi), F) = \text{colim}(\phi, F)$ because $\mathcal{P}\mathbb{A}(Y_{\mathbb{A}}-, \phi) = \phi$. Conversely, supposing that \mathbb{B} allows colimits of F weighted by presheaves on \mathbb{A} , $\text{colim}(\mathcal{P}\mathbb{A}(Y_{\mathbb{A}}-, -), F)$ exists because, for all $\phi = \mathcal{P}\mathbb{A}(Y_{\mathbb{A}}-, \phi)$, $\text{colim}(\mathcal{P}\mathbb{A}(Y_{\mathbb{A}}-, \phi), F)$ exists (see 5.2).

Since $\mathcal{P}\mathbb{A}$ is cocomplete, $\langle Y_{\mathbb{A}}, F \rangle$ exists, is pointwise, and can thus be computed as $\langle Y_{\mathbb{A}}, F \rangle(b) \cong \text{colim}(\mathbb{B}(F-, b), Y_{\mathbb{A}}) \cong \mathbb{B}(F-, b)$. It is then a matter of applying 4.2 to prove the adjunction:

$$\begin{aligned} & \langle F, Y_{\mathbb{A}} \rangle \dashv \langle Y_{\mathbb{A}}, F \rangle \\ \iff & \forall \phi \in \mathcal{P}\mathbb{A}, \forall b \in \mathbb{B} : \mathbb{B}(\langle F, Y_{\mathbb{A}} \rangle(\phi), b) = \mathcal{P}\mathbb{A}(\phi, \langle Y_{\mathbb{A}}, F \rangle(b)) \\ \iff & \forall \phi \in \mathcal{P}\mathbb{A}, \forall b \in \mathbb{B} : \mathbb{B}(\text{colim}(\phi, F), b) = [\phi, \mathbb{B}(F-, b)] \end{aligned}$$

which holds by the definition of colimit.

Finally, by fully faithfulness of $Y_{\mathbb{A}}$ and 6.7 it follows that F factors through $Y_{\mathbb{A}}$ as $\langle F, Y_{\mathbb{A}} \rangle$. Would now $G: \mathcal{P}\mathbb{A} \rightarrow \mathbb{B}$ be another cocontinuous functor such that $F \cong G \circ Y_{\mathbb{A}}$ then – by cocontinuity and using the fact that any presheaf $\phi \in \mathcal{P}\mathbb{A}$ is canonically the colimit of representables – G and $\langle F, Y_{\mathbb{A}} \rangle$ agree on all objects of $\mathcal{P}\mathbb{A}$:

$$\begin{aligned} G(\phi) &= G(\text{colim}(\phi, Y_{\mathbb{A}})) \\ &\cong \text{colim}(\phi, G \circ Y_{\mathbb{A}}) \\ &\cong \text{colim}(\phi, F) \\ &= \langle F, Y_{\mathbb{A}} \rangle(\phi). \end{aligned}$$

□

Corollary 6.10 *A \mathcal{Q} -category \mathbb{A} is cocomplete if and only if $Y_{\mathbb{A}}: \mathbb{A} \rightarrow \mathcal{P}\mathbb{A}$ is a right adjoint in $\text{Cat}(\mathcal{Q})$.*

Proof: If $Y_{\mathbb{A}}$ is right adjoint, apply 5.13 to $Y_{\mathbb{A}}$, using 6.3 and 6.4. If \mathbb{A} is cocomplete, apply 6.9 to the identity functor $1_{\mathbb{A}}: \mathbb{A} \rightarrow \mathbb{A}$: $\langle 1_{\mathbb{A}}, Y_{\mathbb{A}} \rangle \dashv \langle Y_{\mathbb{A}}, 1_{\mathbb{A}} \rangle = Y_{\mathbb{A}}$. □

Free cocompletion

Applying 6.9 we easily obtain that, for two \mathcal{Q} -categories \mathbb{A} and \mathbb{B} , with \mathbb{B} cocomplete, any functor $F: \mathbb{A} \rightarrow \mathbb{B}$ factors through $Y_{\mathbb{A}}: \mathbb{A} \rightarrow \mathcal{P}\mathbb{A}$ by the essentially unique cocontinuous – even left adjoint – functor $\langle F, Y_{\mathbb{A}} \rangle: \mathcal{P}\mathbb{A} \rightarrow \mathbb{B}$. Let now $\text{Cocont}(\mathcal{Q})$ denote the sub-2-category of $\text{Cat}(\mathcal{Q})$ whose objects are the cocomplete \mathcal{Q} -categories,

and whose morphisms are the cocontinuous functors, or equivalently (by 6.8) the left adjoint ones; there is a forgetful 2-functor $\mathcal{U}: \mathbf{Cocont}(\mathcal{Q}) \rightarrow \mathbf{Cat}(\mathcal{Q})$. The above then says that, for \mathcal{Q} -categories \mathbb{A} and \mathbb{B} , with \mathbb{B} cocomplete, the Yoneda embedding $Y_{\mathbb{A}}: \mathbb{A} \rightarrow \mathcal{P}\mathbb{A}$ induces a natural equivalence of orders

$$- \circ Y_{\mathbb{A}}: \mathbf{Cocont}(\mathcal{Q})(\mathcal{P}\mathbb{A}, \mathbb{B}) \xrightarrow{\sim} \mathbf{Cat}(\mathcal{Q})(\mathbb{A}, \mathbb{B})$$

with inverse $F \mapsto \langle F, Y_{\mathbb{A}} \rangle$.

Proposition 6.11 *The presheaf construction provides a left (bi)adjoint to the inclusion of $\mathbf{Cocont}(\mathcal{Q})$ in $\mathbf{Cat}(\mathcal{Q})$: $\mathcal{P} \dashv \mathcal{U}: \mathbf{Cocont}(\mathcal{Q}) \xleftrightarrow{\quad} \mathbf{Cat}(\mathcal{Q})$.*

For any two \mathcal{Q} -categories \mathbb{A} and \mathbb{B} , we have – by 6.1 and the above – equivalences

$$\mathbf{Dist}(\mathcal{Q})(\mathbb{A}, \mathbb{B}) \xrightarrow{\sim} \mathbf{Cat}(\mathcal{Q})(\mathbb{A}, \mathcal{P}\mathbb{B}) \xrightarrow{\sim} \mathbf{Cocont}(\mathcal{Q})(\mathcal{P}\mathbb{A}, \mathcal{P}\mathbb{B}) \quad (12)$$

sending a $\Phi: \mathbb{A} \dashv \mathbb{B}$ to $\langle F_{\Phi}, Y_{\mathbb{A}} \rangle: \mathcal{P}\mathbb{B} \rightarrow \mathcal{P}\mathbb{A}$ (with $F_{\Phi}: \mathbb{B} \rightarrow \mathcal{P}\mathbb{A}: b \mapsto \Phi(-, b)$ as in 6.1). We can prove more.

Proposition 6.12 *The locally ordered¹⁰ category $\mathbf{Cocont}(\mathcal{Q})$ has stable local colimits, and the action*

$$\mathbf{Dist}(\mathcal{Q}) \rightarrow \mathbf{Cocont}(\mathcal{Q}): \left(\Phi: \mathbb{A} \dashv \mathbb{B} \right) \mapsto \left(\langle F_{\Phi}, Y_{\mathbb{A}} \rangle: \mathcal{P}\mathbb{A} \rightarrow \mathcal{P}\mathbb{B} \right)$$

is a 2-functor which is locally an equivalence.

Proof: We already know that $\mathbf{Cocont}(\mathcal{Q})$ is a 2-category; we must show that it has stable local colimits. By 5.6 we know how to compute suprema in $\mathbf{Cat}(\mathcal{Q})(\mathbb{A}, \mathbb{B})$ whenever \mathbb{B} is cocomplete; we may thus apply this to given arrows $(F_i: \mathbb{A} \rightarrow \mathbb{B})_{i \in I}$ in $\mathbf{Cocont}(\mathcal{Q})$:

$$\bigvee_{i \in I} F_i := \text{colim} \left(\bigvee_{i \in I} \mathbb{B}(-, F_i -), 1_{\mathbb{B}} \right).$$

But we must show that $\bigvee_i F_i$ is still a cocontinuous functor (for *a priori* it is merely a functor); equivalently (by cocompleteness of \mathbb{A}), we may assume that each F_i is a left adjoint in $\mathbf{Cat}(\mathcal{Q})$, and show that $\bigvee_i F_i$ itself is a left adjoint in $\mathbf{Cat}(\mathcal{Q})$. Let us write $F_i \dashv G_i$ for such adjunctions; then, by 5.6 and its dual¹¹,

$$\mathbb{B} \left(\bigvee_i F_i -, - \right) = \bigwedge_i \mathbb{B}(F_i -, -) = \bigwedge_i \mathbb{A}(-, G_i -) = \mathbb{A}(-, \bigwedge_i G_i -).$$

¹⁰ ... but not antisymmetrically so!

¹¹The dual of 5.6 says the following: if \mathbb{A} is a complete category, then the infimum of functors $(G_i: \mathbb{B} \rightarrow \mathbb{A})_{i \in I}$ exists in $\mathbf{Cat}(\mathcal{Q})(\mathbb{B}, \mathbb{A})$, and is given by the $\bigvee_i \mathbb{A}(G_i -, -)$ -weighted limit of $1_{\mathbb{A}}$. This means exactly that this infimum $\bigwedge_i G_i$ satisfies $\mathbb{A}(-, \bigwedge_i G_i -) = \bigwedge_i \mathbb{A}(-, G_i -)$. By 5.10 any complete category is also cocomplete, so this applies in this case!

That is to say, $\bigvee_i F_i \dashv \bigwedge_i G_i$ in $\mathbf{Cat}(\mathcal{Q})$. As for the stability of these local colimits, take for example $(F_i: \mathbb{A} \rightarrow \mathbb{B})_{i \in I}$ and $G: \mathbb{B} \rightarrow \mathbb{C}$ in $\mathbf{Cocont}(\mathcal{Q})$; then

$$\begin{aligned}
G \circ \left(\bigvee_i F_i \right) &= G \circ \operatorname{colim} \left(\bigvee_i \mathbb{B}(-, F_i-), 1_{\mathbb{B}} \right) \\
&\cong \operatorname{colim} \left(\bigvee_i \mathbb{B}(-, F_i-), G \right) \\
&\cong \operatorname{colim} \left(\mathbb{C}(-, G-) \otimes_{\mathbb{B}} \bigvee_i (-, F_i-), 1_{\mathbb{C}} \right) \\
&\cong \operatorname{colim} \left(\bigvee_i (-, G \circ F_i-), 1_{\mathbb{C}} \right) \\
&= \bigvee_i (G \circ F_i)
\end{aligned}$$

because G is cocontinuous. Now consider $F: \mathbb{A} \rightarrow \mathbb{B}$ and $(G_i: \mathbb{B} \rightarrow \mathbb{C})_{i \in I}$, then for any $a \in \mathbb{A}_0$

$$\begin{aligned}
\left(\left(\bigvee_i G_i \right) \circ F \right) (a) &= \operatorname{colim} \left(\bigvee_i \mathbb{C}(-, G_i-), 1_{\mathbb{C}} \right) (Fa) \\
&\cong \operatorname{colim} \left(\bigvee_i \mathbb{C}(-, G_i-) \otimes_{\mathbb{B}} \mathbb{B}(-, Fa), 1_{\mathbb{C}} \right) \\
&\cong \operatorname{colim} \left(\bigvee_i \mathbb{C}(-, G_i(Fa)), 1_{\mathbb{C}} \right) \\
&\cong \operatorname{colim} \left(\bigvee_i \mathbb{C}(-, G_i \circ F-), 1_{\mathbb{C}} \right) (a) \\
&= \left(\bigvee_i (G_i \circ F) \right) (a)
\end{aligned}$$

by properties of the colimit – see 5.2 – so $(\bigvee_i G_i) \circ F = \bigvee_i (G_i \circ F)$.

To prove the functoriality of the action described in the statement of the proposition, first observe that for an identity distributor $\mathbb{A}: \mathbb{A} \dashv \!\!\! \dashv \mathbb{A}$, both $\langle Y_{\mathbb{A}}, Y_{\mathbb{A}} \rangle$ and $1_{\mathcal{P}\mathbb{A}}$ are cocontinuous (left adjoint) factorizations of $Y_{\mathbb{A}}$ through $Y_{\mathbb{A}}$, so – applying 6.11 – at least they are isomorphic functors; $\mathcal{P}\mathbb{A}$ being skeletal implies that this isomorphism is an equality. For $\Phi: \mathbb{A} \dashv \!\!\! \dashv \mathbb{B}$ and $\Psi: \mathbb{B} \dashv \!\!\! \dashv \mathbb{C}$, to check that $\langle F_{\Psi}, Y_{\mathbb{B}} \rangle \circ \langle F_{\Phi}, Y_{\mathbb{A}} \rangle = \langle F_{\Psi \otimes_{\mathbb{B}} \Phi}, Y_{\mathbb{A}} \rangle$ in $\mathbf{Cat}(\mathcal{Q})(\mathcal{P}\mathbb{A}, \mathcal{P}\mathbb{C})$, it suffices to see – again by 6.11 and by skeletality of $\mathcal{P}\mathbb{C}$ – that $\langle F_{\Psi}, Y_{\mathbb{B}} \rangle \circ \langle F_{\Phi}, Y_{\mathbb{A}} \rangle$ is a cocontinuous factorization of $F_{\Psi \otimes_{\mathbb{B}} \Phi}$ through $Y_{\mathbb{A}}$. As composition of left adjoints, $\langle F_{\Psi}, Y_{\mathbb{B}} \rangle \circ \langle F_{\Phi}, Y_{\mathbb{A}} \rangle$ is left adjoint. And since $\langle F_{\Phi}, Y_{\mathbb{A}} \rangle \circ Y_{\mathbb{A}} = F_{\Phi}$, it suffices to show that $\langle F_{\Psi}, Y_{\mathbb{B}} \rangle \circ F_{\Phi} \cong F_{\Psi \otimes_{\mathbb{B}} \Phi}$. But for any $a \in \mathbb{A}$ one calculates that

$$\begin{aligned}
\left(\langle F_{\Psi}, Y_{\mathbb{B}} \rangle \circ F_{\Phi} \right) (a) &= \langle F_{\Psi}, Y_{\mathbb{B}} \rangle \left(\Phi(-, a) \right) \\
&= \operatorname{colim} \left(\Phi(-, a), F_{\Psi} \right) \\
&= \left(\Psi \otimes_{\mathbb{B}} \Phi \right) (-, a) \\
&= F_{\Psi \otimes_{\mathbb{B}} \Phi} (a).
\end{aligned}$$

That this functor is really a 2-functor, and that it is locally an equivalence, follows from the preceding remarks, in particular (12). \square

Restricting to skeletal cocomplete \mathcal{Q} -categories, $\mathbf{Cocont}_{\text{skel}}(\mathcal{Q})$ is a quantaloid and the 2-functor above corestricts to a quantaloid homomorphism $\mathbf{Dist}(\mathcal{Q}) \rightarrow \mathbf{Cocont}_{\text{skel}}(\mathcal{Q})$ that induces sup-isomorphisms between the hom-sup-lattices.

Example 6.13 For a 2-category \mathbb{A} , i.e. an ordered set, $\mathcal{P}\mathbb{A}$ is set of down-sets of \mathbb{A} , ordered by inclusion. The Yoneda embedding $Y_{\mathbb{A}}: \mathbb{A} \rightarrow \mathcal{P}\mathbb{A}$ sends an element to the principal down-set that it determines. An eventual left adjoint to $Y_{\mathbb{A}}$ is “taking the supremum”. The isomorphism $\mathbf{Dist}(\mathbf{2})(\mathbb{A}, \mathbb{B}) \cong \mathbf{Cocont}_{\text{skel}}(\mathbf{2})(\mathcal{P}\mathbb{A}, \mathcal{P}\mathbb{B})$ says that an ideal relation between given orders is the same thing as a sup-morphism between the sup-lattices of down-sets of those orders. In fact, $\mathbf{Cocont}_{\text{skel}}(\mathbf{2}) = \mathbf{Sup}$.

Covariant presheaves, free completion

The results in the previous sections may be dualized; one obtains that “the \mathcal{Q} -category of covariant presheaves on \mathbb{A} is \mathbb{A} ’s free completion in $\mathbf{Cat}(\mathcal{Q})$ ”. Let us quickly do this exercise.

A covariant presheaf of type $C \in \mathcal{Q}$ on a \mathcal{Q} -category \mathbb{A} is a distributor $\phi: \mathbb{A} \rightarrow *C$. Covariant presheaves form the object-set of a \mathcal{Q} -category $\mathcal{P}^{\dagger}\mathbb{A}$, whose hom-arrows are, for $\phi: \mathbb{A} \rightarrow *C$ and $\psi: \mathbb{A} \rightarrow *C'$,

$$\mathcal{P}^{\dagger}\mathbb{A}(\psi, \phi) = \text{single element of } \{\phi, \psi\} \text{ in } \mathbf{Dist}(\mathcal{Q}).$$

This \mathcal{Q} -category satisfies

$$\text{for every } \mathcal{Q}\text{-category } \mathbb{C}, \mathbf{Dist}(\mathcal{Q})(\mathbb{A}, \mathbb{C}) \simeq \mathbf{Cat}(\mathcal{Q})^{\text{co}}(\mathbb{C}, \mathcal{P}^{\dagger}\mathbb{A}), \quad (13)$$

and it is complete. There is a Yoneda embedding $Y_{\mathbb{A}}^{\dagger}: \mathbb{A} \rightarrow \mathcal{P}^{\dagger}\mathbb{A}$, sending an object $a \in \mathbb{A}$ to the representable distributor $\mathbb{A}(a, -): \mathbb{A} \rightarrow *ta$, which is fully faithful. \mathbb{A} is complete if and only if $Y_{\mathbb{A}}^{\dagger}$ is a left adjoint in $\mathbf{Cat}(\mathcal{Q})$; but in any case is $Y_{\mathbb{A}}^{\dagger}$ cocontinuous.

Continuous functors whose domain is a complete \mathcal{Q} -category, coincide with the right adjoints. Denoting $\mathbf{Cont}(\mathcal{Q})$ for the sub-2-category of $\mathbf{Cat}(\mathcal{Q})$ whose objects are complete \mathcal{Q} -categories and arrows are continuous functors, we have

$$\mathcal{P}^{\dagger} \dashv \mathcal{U}: \mathbf{Cont}(\mathcal{Q}) \xleftrightarrow{\quad} \mathbf{Cat}(\mathcal{Q});$$

that is, $\mathcal{P}^{\dagger}\mathbb{A}$ is the free completion of \mathbb{A} in $\mathbf{Cat}(\mathcal{Q})$. Furthermore, $\mathbf{Cont}(\mathcal{Q})$ has stable local limits, and there is 2-functor, which is locally an equivalence, like so: $\mathbf{Dist}(\mathcal{Q}) \rightarrow \mathbf{Cont}(\mathcal{Q})^{\text{coop}}$ sends a distributor $\Phi: \mathbb{A} \rightarrow \mathbb{B}$ to the right Kan extension $(F^{\Phi}, Y_{\mathbb{A}}^{\dagger}): \mathcal{P}^{\dagger}\mathbb{B} \rightarrow \mathcal{P}^{\dagger}\mathbb{A}$, where $F^{\Phi}: \mathbb{B} \rightarrow \mathcal{P}^{\dagger}\mathbb{A}$ is determined by Φ through the equivalence in (13).

Since a \mathcal{Q} -category is complete if and only if it is cocomplete, and since between such categories continuous (cocontinuous) functors coincide with right adjoints (left adjoints), there is an isomorphism of (locally cocompletely ordered) 2-categories

$$\text{Cocont}(\mathcal{Q}) \xrightarrow{\sim} \text{Cont}(\mathcal{Q})^{\text{coop}}: \left(F: \mathbb{A} \longrightarrow \mathbb{B} \right) \longleftrightarrow \left(F^*: \mathbb{B} \longrightarrow \mathbb{A} \right)$$

where $F \dashv F^*$ in $\text{Cat}(\mathcal{Q})$. Considering only skeletal objects, this restricts to an isomorphism of quantaloids $\text{Cocont}_{\text{skel}}(\mathcal{Q}) \cong \text{Cont}_{\text{skel}}^{\text{coop}}(\mathcal{Q})$.

Assembling previous results we obtain that: for a \mathcal{Q} -category \mathbb{A} , $Y_{\mathbb{A}}: \mathbb{A} \longrightarrow \mathcal{P}\mathbb{A}$ is a right adjoint if and only if $Y_{\mathbb{A}}^{\dagger}: \mathbb{A} \longrightarrow \mathcal{P}^{\dagger}\mathbb{A}$ is a left adjoint; this is precisely the case when \mathbb{A} is (co)complete. It is interesting to take a closer look at this result. First observe that, in any case, there is an adjunction

$$\begin{array}{ccc} & [-, \mathbb{A}] & \\ & \curvearrowright & \\ \mathcal{P}\mathbb{A} & \perp & \mathcal{P}^{\dagger}\mathbb{A} \\ & \curvearrowleft & \\ & \{-, \mathbb{A}\} & \end{array}$$

in $\text{Cat}(\mathcal{Q})$, where the functors involved are obtained by calculating $\{-, -\}$ and $[-, -]$ in $\text{Dist}(\mathcal{Q})$:

$$\begin{aligned} [-, \mathbb{A}]: \mathcal{P}\mathbb{A} &\longrightarrow \mathcal{P}^{\dagger}\mathbb{A}: \left(\phi: *_A \dashv\!\!\dashv \!\!\!\dashv \mathbb{A} \right) \mapsto \left([\phi, \mathbb{A}]: \mathbb{A} \dashv\!\!\dashv \!\!\!\dashv *_A \right), \\ \{-, \mathbb{A}\}: \mathcal{P}^{\dagger}\mathbb{A} &\longrightarrow \mathcal{P}\mathbb{A}: \left(\psi: \mathbb{A} \dashv\!\!\dashv \!\!\!\dashv *_A \right) \mapsto \left(\{\psi, \mathbb{A}\}: *_A \dashv\!\!\dashv \!\!\!\dashv \mathbb{A} \right). \end{aligned}$$

Now considering the diagram of \mathcal{Q} -categories and functors

$$\begin{array}{ccc} & \mathbb{A} & \\ R \swarrow & \dashv\!\!\dashv \!\!\!\dashv & \searrow L \\ \mathcal{P}^{\dagger}\mathbb{A} & \xleftarrow{Y_{\mathbb{A}}^{\dagger}} \mathbb{A} \xrightarrow{Y_{\mathbb{A}}} & \mathcal{P}\mathbb{A} \\ & \{-, \mathbb{A}\} & \\ & \xrightarrow{[-, \mathbb{A}]} & \end{array}$$

we have on the one hand that, if $L \dashv Y_{\mathbb{A}}$ is known, then $R := L \circ \{-, \mathbb{A}\}$ is right adjoint to $Y_{\mathbb{A}}^{\dagger}$; and dually, if $Y_{\mathbb{A}}^{\dagger} \dashv R$ is known, then $L := R \circ [-, \mathbb{A}]$ is left adjoint to $Y_{\mathbb{A}}$. Actually, $L(\phi) = \text{colim}(\phi, 1_{\mathbb{A}})$ and $R(\psi) = \text{lim}(\psi, 1_{\mathbb{A}})$ (whenever one, thus also the other, exists), so that the *crux* of this construction is really the statement in 5.8.

Example 6.14 Take $\mathbf{2}$ -categories, then $\text{Cont}(\mathbf{2}) \simeq \text{Inf} = \text{Cont}_{\text{skel}}(\mathbf{2})$. For a $\mathbf{2}$ -category \mathbb{A} , $\mathcal{P}^{\dagger}\mathbb{A}$ is the set of up-sets of \mathbb{A} , ordered by containment (reverse inclusion); $Y_{\mathbb{A}}^{\dagger}$ sends an element of \mathbb{A} to the corresponding principal up-set. An eventual right adjoint to $Y_{\mathbb{A}}^{\dagger}$ is “infimum”. It is well-known that $\text{Sup} \cong \text{Inf}^{\text{coop}}$ in QUANT by passing from left-adjoints to right-adjoints in $\text{Cat}(\mathbf{2})$. The adjunction between

$\mathcal{P}\mathbb{A}$ (down-sets of \mathbb{A} , ordered by inclusion) and $\mathcal{P}^\dagger\mathbb{A}$ (up-sets of \mathbb{A} , ordered by containment) is constituted by the left adjoint that sends a down-set to the up-set of its upper bounds, and the right adjoint that sends an up-set to the down-set of its lower bounds.

Example 6.15 For a \mathcal{Q} -object X , the category of covariant presheaves on $*_X$ is denoted $\mathcal{P}^\dagger X$ rather than $\mathcal{P}^\dagger(*_X)$ (cf. 3.9).

7 Cauchy completion and Morita equivalence

Cauchy complete categories

A left adjoint distributor $\Phi: \mathbb{C} \dashv\!\!\dashv \mathbb{A}$ is often called a *Cauchy distributor* (into \mathbb{A}); we will systematically denote its right adjoint as Φ^* :

$$\begin{array}{ccc} & \Phi & \\ & \circlearrowright & \\ \mathbb{A} & & \mathbb{B} \\ & \circlearrowleft & \\ & \Phi^* & \end{array}$$

In particular, a *Cauchy presheaf* $\phi: *_C \dashv\!\!\dashv \mathbb{A}$ is a contravariant presheaf with a right adjoint $\phi^*: \mathbb{A} \dashv\!\!\dashv *_C$, whose elements are $\phi^*(a): ta \rightarrow C$.

A Cauchy distributor $\Phi: \mathbb{C} \dashv\!\!\dashv \mathbb{A}$ is said to *converge* (to a functor $F: \mathbb{C} \rightarrow \mathbb{A}$) if (there exists a functor $F: \mathbb{C} \rightarrow \mathbb{A}$ such that) $\Phi = \mathbb{B}(-, F-)$ —or equivalently, $\Phi^* = \mathbb{B}(F-, -)$. A Cauchy distributor $\Phi: \mathbb{C} \dashv\!\!\dashv \mathbb{A}$ need not converge, but if it does then the functor $F: \mathbb{C} \rightarrow \mathbb{A}$ that it converges to, is essentially unique. We are interested in those \mathcal{Q} -categories in which “all Cauchy distributors converge”: say that \mathbb{A} is *Cauchy complete* if, for all \mathbb{C} , any Cauchy distributor $\Phi: \mathbb{C} \dashv\!\!\dashv \mathbb{A}$ converges. In other words, letting $\text{Map}(\text{Dist}(\mathcal{Q}))(\mathbb{C}, \mathbb{A})$ denote the full subcategory of $\text{Dist}(\mathcal{Q})(\mathbb{C}, \mathbb{A})$ whose objects are the Cauchy distributors (“maps”), \mathbb{A} is Cauchy complete if and only if, for every \mathbb{C} , the mapping

$$\text{Cat}(\mathcal{Q})(\mathbb{C}, \mathbb{A}) \longrightarrow \text{Map}(\text{Dist}(\mathcal{Q}))(\mathbb{C}, \mathbb{A}): F \mapsto \mathbb{A}(-, F-)$$

is surjective; recalling that it is always “essentially injective”, we thus ask for it to be an equivalence.

Fortunately, to have Cauchy completeness, convergence of the Cauchy presheaves suffices!

Proposition 7.1 *A \mathcal{Q} -category \mathbb{A} is Cauchy complete if and only if all Cauchy presheaves on \mathbb{A} converge (i.e. are representable).*

Proof: We only need to prove the “if”. Let $\Phi \dashv\!\!\dashv \Phi^*: \mathbb{A} \xrightarrow{\text{L}} \mathbb{C}$, then for each $c \in \mathbb{C}_0$, $\Phi(-, c) \dashv\!\!\dashv \Phi^*(c, -): \mathbb{A} \xrightarrow{\text{L}} \mathbb{C}$, because $\Phi \otimes_{\mathbb{C}} \mathbb{C}(-, c) = \Phi(-, c)$ and $\mathbb{C}(c, -) \otimes_{\mathbb{C}} \Phi^* = \Phi^*(c, -)$, and by composition of adjoints. By assumption there exists for each $c \in \mathbb{C}_0$

a functor $Fc: *_c \rightarrow \mathbb{A}$ – that we will henceforth identify with the single element of type tc that it picks out – such that $\mathbb{A}(-, Fc) = \Phi(-, c)$ or equivalently, $\mathbb{A}(Fc, -) = \Phi^*(c, -)$. But the object mapping $\mathbb{C}_0 \rightarrow \mathbb{A}_0: c \mapsto Fc$ is functorial: since $\mathbb{C} \leq \Phi^* \otimes_{\mathbb{A}} \Phi$ it follows that

$$\mathbb{C}(c', c) \leq \Phi^*(c', -) \otimes_{\mathbb{A}} \Phi(-, c) = \mathbb{A}(Fc', -) \otimes_{\mathbb{A}} \mathbb{A}(-, Fc) = \mathbb{A}(Fc', Fc).$$

Clearly $\Phi \dashv \Phi^*$ converges to the functor $F: \mathbb{C} \rightarrow \mathbb{A}: c \mapsto Fc$. \square

The next proposition explains Cauchy completeness as “admitting all Cauchy-weighted colimits”.

Proposition 7.2 *A \mathcal{Q} -category is Cauchy complete if and only if it admits all colimits weighted by a Cauchy distributor, if and only if it admits all colimits weighted by a Cauchy (contravariant) presheaf.*

Proof : Let \mathbb{B} be Cauchy complete; given a Cauchy distributor $\Phi: \mathbb{C} \dashv \mathbb{A}$ and a functor $F: \mathbb{A} \rightarrow \mathbb{B}$, the Φ -weighted colimit of F is the functor $K: \mathbb{C} \rightarrow \mathbb{B}$ to which the Cauchy distributor $\mathbb{B}(-, F-) \otimes_{\mathbb{A}} \Phi$ converges:

$$\mathbb{B}(K-, -) = \Phi^* \otimes_{\mathbb{A}} \mathbb{B}(F-, -) = \left[\Phi, \mathbb{B}(F-, -) \right].$$

Suppose now that \mathbb{B} admits all colimits weighted by a Cauchy presheaf; then every such Cauchy presheaf is representable because $\phi: *_C \dashv \mathbb{B}$ (with $\phi \dashv \phi^*$) converges to $\text{colim}(\phi, 1_{\mathbb{B}})$:

$$\mathbb{B}\left(\text{colim}(\phi, 1_{\mathbb{B}})-, -\right) = \left[\phi, \mathbb{B}(1_{\mathbb{B}}-, -) \right] = \phi^* \otimes_{\mathbb{B}} \mathbb{B}(-, -) = \phi^*.$$

By 7.1 \mathbb{B} is Cauchy complete. (The remaining implication is trivial.) \square

‘Cauchy completeness’ is a self-dual notion: a \mathcal{Q} -category \mathbb{A} is Cauchy complete if and only if the \mathcal{Q}^{op} -category \mathbb{A}^{op} is. (This really follows directly from the definition.) Therefore we have – by dualizing the statement of 7.2, using that ‘Cauchy completeness’ is a self-dual notion – at once the following.

Proposition 7.3 *A \mathcal{Q} -category \mathbb{A} is Cauchy complete if and only if it admits all limits weighted by a right adjoint distributor, if and only if it admits all limits weighted by a right adjoint (covariant) presheaf.*

In the rest of this section we work in terms of colimits.

Example 7.4 Every $\mathbf{2}$ -enriched category \mathbb{A} is Cauchy complete: a down-set of \mathbb{A} (i.e. a contravariant presheaf on \mathbb{A}) is Cauchy if and only if it is principal (i.e. a representable presheaf).

Example 7.5 The $\text{Rel}(\Omega)$ -category associated to a sheaf on a locale Ω (see 3.11) is (skeletal and) Cauchy complete. In fact, it is also *symmetric* in the sense that it equals its opposite (which makes sense because $\text{Rel}(\Omega)^{\text{op}} = \text{Rel}(\Omega)$). [Walters, 1981] proves that sheaves on Ω are *precisely* the symmetric, skeletal, Cauchy complete $\text{Rel}(\Omega)$ -categories. Dropping symmetry and skeletality, Cauchy complete $\text{Rel}(\Omega)$ -categories are ordered sheaves on Ω [Betti *et al.*, 1983; Stubbe, 2004c].

Example 7.6 Consider again Lawvere’s generalized metric spaces (see 3.12); let \mathbb{A} denote such a space. In [Lawvere, 1973] it is proved that a left adjoint distributor from a one-point space into \mathbb{A} is precisely (an equivalence class of) a Cauchy sequence in \mathbb{A} —and it is therefore that left adjoint distributors are also called Cauchy distributors. Cauchy completeness of \mathbb{A} as enriched category coincides with its Cauchy completeness as metric space (“all Cauchy sequences/distributors converge”).

Cauchy completing a category

Not every \mathcal{Q} -category \mathbb{A} is Cauchy complete; still we are interested in “classifying” the Cauchy distributors on \mathbb{A} : we want to construct a \mathcal{Q} -category \mathbb{A}_{cc} such that

$$\text{for every } \mathcal{Q}\text{-category } \mathbb{C}, \text{Map}(\text{Dist}(\mathcal{Q}))(\mathbb{C}, \mathbb{A}) \simeq \text{Cat}(\mathcal{Q})(\mathbb{C}, \mathbb{A}_{\text{cc}}). \quad (14)$$

Much like the construction of $\mathcal{P}\mathbb{A}$ we have the following proposition (the proof of which is much like that of 6.1, so it is omitted).

Proposition 7.7 *For any \mathcal{Q} -category \mathbb{A} , the “Cauchy completion \mathbb{A}_{cc} of \mathbb{A} ” is, by definition, the full subcategory of $\mathcal{P}\mathbb{A}$ determined by the Cauchy presheaves on \mathbb{A} :*

$$(\mathbb{A}_{\text{cc}})_0 = \{\phi \in (\mathcal{P}\mathbb{A})_0 \mid \phi \text{ is Cauchy}\}.$$

This \mathcal{Q} -category is skeletal and it satisfies (14):

- for a Cauchy distributor $\Phi: \mathbb{C} \dashrightarrow \mathbb{A}$ the corresponding functor $F_\Phi: \mathbb{C} \rightarrow \mathbb{A}_{\text{cc}}$ maps $c \in \mathbb{C}_0$ onto the Cauchy presheaf $\Phi(-, c): tc \dashrightarrow \mathbb{A}$;
- and for a functor $F: \mathbb{C} \rightarrow \mathbb{A}_{\text{cc}}$ the corresponding Cauchy distributor $\Phi_F: \mathbb{C} \dashrightarrow \mathbb{A}$ has elements, for $(c, a) \in \mathbb{C}_0 \times \mathbb{A}_0$, $\Phi_F(a, c) = F(c)(a)$ (and its right adjoint has elements $\Phi_F^*(c, a) = F(c)^*(a)$).

Note that the hom-arrows in \mathbb{A}_{cc} are identical to those in $\mathcal{P}\mathbb{A}$, but since objects $\phi, \psi \in \mathbb{A}_{\text{cc}}$ have right adjoints in $\text{Dist}(\mathcal{Q})$ we may write (with slight abuse of notation) that $\mathbb{A}_{\text{cc}}(\psi, \phi) = \psi^* \otimes_{\mathbb{A}} \phi$. This will be a helpful trick in many of the calculations that follow.

Plugging the identity distributor $\mathbb{A}: \mathbb{A} \dashrightarrow \mathbb{A}$ into the equivalence (14) gives us a functor

$$i_{\mathbb{A}}: \mathbb{A} \rightarrow \mathbb{A}_{\text{cc}}: a \mapsto \left(\mathbb{A}(-, a): *_{ta} \dashrightarrow \mathbb{A} \right)$$

which is precisely the factorization of the Yoneda embedding $Y_{\mathbb{A}}: \mathbb{A} \rightarrow \mathcal{P}\mathbb{A}$ over the full inclusion $j_{\mathbb{A}}: \mathbb{A}_{\text{cc}} \rightarrow \mathcal{P}\mathbb{A}$ that defined \mathbb{A}_{cc} . An alternative for the classifying property in (14) is then: for any \mathbb{C} , a distributor $\Phi: \mathbb{C} \dashv\vdash \mathbb{A}$ is Cauchy if and only if the corresponding functor $F_{\Phi}: \mathbb{C} \rightarrow \mathcal{P}\mathbb{A}$ (as in 6.1) factors through $j_{\mathbb{A}}: \mathbb{A}_{\text{cc}} \rightarrow \mathcal{P}\mathbb{A}$. It follows too that $i_{\mathbb{A}}$ enjoys properties similar to those of $Y_{\mathbb{A}}$ (especially 6.3 and 6.5).

Proposition 7.8 *For any Cauchy presheaf $\phi: *_{\mathbb{C}} \dashv\vdash \mathbb{A}$ and any object $a \in \mathbb{A}_0$, $\mathbb{A}_{\text{cc}}(i_{\mathbb{A}}(a), \phi) = \phi(a)$ and $\mathbb{A}_{\text{cc}}(\phi, i_{\mathbb{A}}(a)) = \phi^*(a)$. In particular is $i_{\mathbb{A}}: \mathbb{A} \rightarrow \mathbb{A}_{\text{cc}}$ fully faithful.*

Proposition 7.9 *Every Cauchy presheaf on a \mathcal{Q} -category \mathbb{A} is canonically the colimit of representables in \mathbb{A}_{cc} : for $\phi: *_{\mathbb{C}} \dashv\vdash \mathbb{A}$ Cauchy, the ϕ -weighted colimit of $i_{\mathbb{A}}: \mathbb{A} \rightarrow \mathbb{A}_{\text{cc}}$ (exists and) is ϕ itself. In other words, $\text{colim}(\phi, i_{\mathbb{A}}) = \phi$ (where we may write an equality instead of merely an isomorphism, for \mathbb{A}_{cc} is skeletal).*

Up to now we have encountered many similarities between $Y_{\mathbb{A}}: \mathbb{A} \rightarrow \mathcal{P}\mathbb{A}$ and $i_{\mathbb{A}}: \mathbb{A} \rightarrow \mathbb{A}_{\text{cc}}$; but here are two remarkable differences.

Proposition 7.10 *A \mathcal{Q} -category \mathbb{A} is Cauchy complete if and only if $i_{\mathbb{A}}: \mathbb{A} \rightarrow \mathbb{A}_{\text{cc}}$ is an essentially surjective functor, if and only if it is an equivalence in $\text{Cat}(\mathcal{Q})$ ¹².*

Proof: Since $i_{\mathbb{A}}: \mathbb{A} \rightarrow \mathbb{A}_{\text{cc}}$ is fully faithful, it is clear that it is an equivalence if and only if it is essentially surjective. But the essential surjectivity, saying that any $\phi \in \mathbb{A}_{\text{cc}}$ is isomorphic to $i_{\mathbb{A}}(a)$ for some $a \in \mathbb{A}$, is precisely the statement in 7.1. \square

Proposition 7.11 *Any \mathcal{Q} -category \mathbb{A} is isomorphic to its Cauchy completion in the quantaloid $\text{Dist}(\mathcal{Q})$ ¹³.*

Proof: $i_{\mathbb{A}}: \mathbb{A} \rightarrow \mathbb{A}_{\text{cc}}$ is a fully faithful functor, so the unit of the induced adjoint pair of distributors $\mathbb{A}_{\text{cc}}(-, i_{\mathbb{A}}-) \dashv \mathbb{A}_{\text{cc}}(i_{\mathbb{A}}-, -)$ is an equality. It suffices to prove that also its co-unit is an equality. Thereto, consider $\phi, \psi \in (\mathbb{A}_{\text{cc}})_0$ and calculate that

$$\begin{aligned}
\mathbb{A}_{\text{cc}}(\psi, i_{\mathbb{A}}-) \otimes_{\mathbb{A}} \mathbb{A}_{\text{cc}}(i_{\mathbb{A}}-, \phi) &= \bigvee_{a \in \mathbb{A}_0} \mathbb{A}_{\text{cc}}(\psi, \mathbb{A}(-, a)) \circ \mathbb{A}_{\text{cc}}(\mathbb{A}(-, a), \phi) \\
&= \psi^* \otimes_{\mathbb{A}} \bigvee_{a \in \mathbb{A}_0} (\mathbb{A}(-, a) \circ \mathbb{A}(a, -)) \otimes_{\mathbb{A}} \phi \\
&= \psi^* \otimes_{\mathbb{A}} \mathbb{A} \otimes_{\mathbb{A}} \phi \\
&= \psi^* \otimes_{\mathbb{A}} \phi \\
&= \mathbb{A}_{\text{cc}}(\psi, \phi).
\end{aligned}$$

That is to say, $\mathbb{A}_{\text{cc}}(-, i_{\mathbb{A}}-) \otimes_{\mathbb{A}} \mathbb{A}_{\text{cc}}(i_{\mathbb{A}}-, -) = \mathbb{A}_{\text{cc}}$, as wanted. \square

¹²Cocompleteness of \mathbb{A} is in general not equivalent to $Y_{\mathbb{A}}: \mathbb{A} \rightarrow \mathcal{P}\mathbb{A}$ being an equivalence in $\text{Cat}(\mathcal{Q})$!

¹³But \mathbb{A} needn't be isomorphic to $\mathcal{P}\mathbb{A}$ in $\text{Dist}(\mathcal{Q})$!

A direct consequence of the above is that $\text{Dist}(\mathcal{Q})$ is equivalent to its full subquantaloid $\text{Dist}_{\text{cc}}(\mathcal{Q})$ determined by the Cauchy complete categories.

The following result, although it uses 7.11 in its proof, may be considered analogous to 6.4.

Proposition 7.12 *For any \mathbb{A} , the Cauchy completion \mathbb{A}_{cc} is Cauchy complete.*

Proof: It suffices to prove that any Cauchy presheaf on \mathbb{A}_{cc} is representable: for any Cauchy $\Phi: *_C \dashv\!\rightarrow \mathbb{A}_{\text{cc}}$ we must find a Cauchy $\phi: *_C \dashv\!\rightarrow \mathbb{A}$ such that $\mathbb{A}_{\text{cc}}(-, \phi) = \Phi$. Using $\mathbb{A} \cong \mathbb{A}_{\text{cc}}$ in $\text{Dist}(\mathcal{Q})$ (see 7.11) we put $\phi := \mathbb{A}_{\text{cc}}(i_{\mathbb{A}} -, -) \otimes_{\mathbb{A}_{\text{cc}}} \Phi$,

$$\begin{array}{ccc} *_C & \xrightarrow{\Phi} & \mathbb{A}_{\text{cc}} \\ & \searrow & \uparrow \mathbb{A}_{\text{cc}}(i_{\mathbb{A}} -, -) \\ & & \mathbb{A} \end{array}$$

ϕ

which is Cauchy because it is the composition of Cauchy distributors ($\mathbb{A}_{\text{cc}}(i_{\mathbb{A}} -, -)$ is not only right but also left adjoint because it is invertible). Now for any $\psi \in \mathbb{B}_{\text{cc}}$,

$$\begin{aligned} \mathbb{A}_{\text{cc}}(\psi, \phi) &= \psi^* \otimes_{\mathbb{A}} \phi \\ &= \psi^* \otimes_{\mathbb{A}} \mathbb{A}_{\text{cc}}(i_{\mathbb{A}} -, -) \otimes_{\mathbb{A}_{\text{cc}}} \Phi \\ &= \mathbb{A}_{\text{cc}}(\psi, i_{\mathbb{A}} -) \otimes_{\mathbb{A}} \mathbb{A}_{\text{cc}}(i_{\mathbb{A}} -, -) \otimes_{\mathbb{A}_{\text{cc}}} \Phi \\ &= \mathbb{A}_{\text{cc}}(\psi, -) \otimes_{\mathbb{A}_{\text{cc}}} \Phi \\ &= \Phi(\psi), \end{aligned}$$

so ϕ indeed represents Φ . □

In view of the examples, in particular 7.5, it is tempting to think of the Cauchy completion $\mathbb{A} \mapsto \mathbb{A}_{\text{cc}}$ of a \mathcal{Q} -category as a sheafification. The following will only strengthen that intuition.

The universality of the Cauchy completion

The proof of the following is analogous to that of 6.9, and therefore it is omitted.

Proposition 7.13 *A functor $F: \mathbb{A} \rightarrow \mathbb{B}$ has a pointwise left Kan extension along $i_{\mathbb{A}}: \mathbb{A} \rightarrow \mathbb{A}_{\text{cc}}$ if and only if, for every $\phi \in \mathbb{A}_{\text{cc}}$, the ϕ -weighted colimit of F exists; in this case $\langle F, i_{\mathbb{A}} \rangle \circ i_{\mathbb{A}} \cong F$ ¹⁴. Actually, $\langle F, i_{\mathbb{A}} \rangle$ is the essentially unique factorization of F through $i_{\mathbb{A}}$.*

In other words, denoting $\text{Cat}_{\text{cc}}(\mathcal{Q})$ for the full sub-2-category of $\text{Cat}(\mathcal{Q})$ determined by the Cauchy complete categories, we have for \mathcal{Q} -categories \mathbb{A} and \mathbb{B} , with \mathbb{B} Cauchy complete, an equivalence induced by composition with $i_{\mathbb{A}}: \mathbb{A} \rightarrow \mathbb{A}_{\text{cc}}$

$$\text{Cat}_{\text{cc}}(\mathcal{Q})(\mathbb{A}_{\text{cc}}, \mathbb{B}) \xrightarrow{\sim} \text{Cat}(\mathcal{Q})(\mathbb{A}, \mathbb{B}): G \mapsto G \circ i_{\mathbb{A}}$$

¹⁴But it is not true in general that $\langle F, i_{\mathbb{A}} \rangle: \mathbb{A}_{\text{cc}} \rightarrow \mathbb{B}$ is a left adjoint!

(with inverse $F \mapsto \langle F, i_{\mathbb{A}} \rangle$).

Proposition 7.14 *Cauchy completing provides a left (bi)adjoint to the embedding of $\text{Cat}_{\text{cc}}(\mathcal{Q})$ in $\text{Cat}(\mathcal{Q})$: $(-)\text{cc} \dashv \mathcal{V}: \text{Cat}_{\text{cc}}(\mathcal{Q}) \xrightarrow{\leftarrow} \text{Cat}(\mathcal{Q})$.*

The 2-functor

$$\text{Cat}_{\text{cc}}(\mathcal{Q}) \longrightarrow \text{Map}(\text{Dist}_{\text{cc}}(\mathcal{Q})) : (F: \mathbb{A} \longrightarrow \mathbb{B}) \mapsto (\mathbb{B}(-, F-): \mathbb{A} \dashv \!\! \dashv \mathbb{B})$$

is the identity on objects, and induces equivalences of the hom-orders: it is a biequivalence. Since $\text{Dist}(\mathcal{Q})$ itself is equivalent to $\text{Dist}_{\text{cc}}(\mathcal{Q})$, we may record that

$$\text{Cat}_{\text{cc}}(\mathcal{Q}) \simeq \text{Map}(\text{Dist}_{\text{cc}}(\mathcal{Q})) \simeq \text{Map}(\text{Dist}(\mathcal{Q})).$$

Finally we wish to discuss the “interplay” between \mathbb{A} , $\mathcal{P}\mathbb{A}$, $\mathcal{P}^\dagger\mathbb{A}$ and \mathbb{A}_{cc} .

Proposition 7.15 *For \mathcal{Q} -categories \mathbb{A} and \mathbb{B} , the following are equivalent:*

1. $\mathbb{A} \cong \mathbb{B}$ in $\text{Dist}(\mathcal{Q})$;
2. $\mathbb{A}_{\text{cc}} \simeq \mathbb{B}_{\text{cc}}$ in $\text{Cat}(\mathcal{Q})$;
3. $\mathcal{P}\mathbb{A} \simeq \mathcal{P}\mathbb{B}$ in $\text{Cat}(\mathcal{Q})$;
4. $\mathcal{P}^\dagger\mathbb{A} \simeq \mathcal{P}^\dagger\mathbb{B}$ in $\text{Cat}(\mathcal{Q})$.

Proof: (1 \Leftrightarrow 2) $\mathbb{A} \cong \mathbb{B}$ in $\text{Dist}(\mathcal{Q})$ implies and is implied by $\mathbb{A}_{\text{cc}} \cong \mathbb{B}_{\text{cc}}$ in $\text{Dist}_{\text{cc}}(\mathcal{Q})$ (using 7.7), which by the biequivalence $\text{Cat}_{\text{cc}}(\mathcal{Q}) \simeq \text{Map}(\text{Dist}_{\text{cc}}(\mathcal{Q}))$ means that $\mathbb{A}_{\text{cc}} \simeq \mathbb{B}_{\text{cc}}$ in $\text{Cat}_{\text{cc}}(\mathcal{Q})$, or in $\text{Cat}(\mathcal{Q})$.

(1 \Leftrightarrow 3) $\mathbb{A} \cong \mathbb{B}$ in $\text{Dist}(\mathcal{Q})$ if and only if $\mathcal{P}\mathbb{A} \simeq \mathcal{P}\mathbb{B}$ in $\text{Cocont}(\mathcal{Q})$ by the fully faithful, locally fully faithful 2-functor $\text{Dist}(\mathcal{Q}) \longrightarrow \text{Cocont}(\mathcal{Q})$ of 6.12; but to give an equivalence between cocomplete categories in $\text{Cocont}(\mathcal{Q})$ is the same as in $\text{Cat}(\mathcal{Q})$ (because the functors constituting the equivalence are always left adjoint, thus co-continuous).

(1 \Leftrightarrow 4) is dual to the previous argument. □

Whenever for two \mathcal{Q} -categories \mathbb{A} and \mathbb{B} the equivalent conditions of 7.15 are fulfilled, then \mathbb{A} is *Morita equivalent* to \mathbb{B} . The morality is then that “a \mathcal{Q} -category is but a presentation of its Cauchy completion”; in particular, if one only cares about \mathcal{Q} -category theory “up to Cauchy completion” (i.e. “up to Morita equivalence”), then one can forget about functors and Cauchy completion and Morita equivalence altogether, and treat $\text{Map}(\text{Dist}(\mathcal{Q}))$ as “the 2-category of \mathcal{Q} -categories and functors”.

8 Appendix: Distributor calculus

Lax (co)limits in a quantaloid

Let \mathcal{Q} denote a quantaloid, and \mathcal{D} a small category. A *lax functor* $F: \mathcal{D} \rightarrow \mathcal{Q}$ is a mapping of objects $\mathcal{D}_0 \rightarrow \mathcal{Q}_0: D \mapsto FD$ together with an action on hom-sets $\mathcal{D}(D, D') \rightarrow \mathcal{Q}(FD, FD'): f \mapsto Ff$ such that

- for all $D \in \mathcal{D}_0$, $1_{FD} \leq F1_D$;
- for all composable $f, g \in \mathcal{D}$, $(Fg \circ Ff) \leq F(g \circ f)$.

Given two such lax functors $F, G: \mathcal{D} \rightrightarrows \mathcal{Q}$, a family $(\theta_D: FD \rightarrow GD)_{D \in \mathcal{D}_0}$ of \mathcal{Q} -arrows constitutes a *lax-natural transformation* $\theta: F \Rightarrow G$ if

- for all $f: D \rightarrow D'$ in \mathcal{D} , $(\theta_{D'} \circ Ff) \geq (Gf \circ \theta_D)$;

and the family is said to constitute an *oplax-natural transformation* if

- for all $f: D \rightarrow D'$ in \mathcal{D} , $(\theta_{D'} \circ Ff) \leq (Gf \circ \theta_D)$.

The collection of lax transfos, resp. oplax transfos, between two parallel lax functors $F, G: \mathcal{D} \rightrightarrows \mathcal{Q}$ constitutes a sup-lattice (with ‘‘componentwise supremum’’); we’ll denote it as $\text{Lax}(F, G)$, resp. $\text{OpLax}(F, G)$. Lax transfos (oplax transfos) may also be composed: this too is done ‘‘componentwise’’. The notions of ‘lax transfo’ and ‘oplax transfo’ are dual in the following sense: two lax functors $F, G: \mathcal{D} \rightrightarrows \mathcal{Q}$ may be thought of as $F^{\text{op}}, G^{\text{op}}: \mathcal{D}^{\text{op}} \rightrightarrows \mathcal{Q}^{\text{op}}$, and then we have that $\text{Lax}(F, G) = \text{OpLax}(G^{\text{op}}, F^{\text{op}})$.

Any (ordinary) functor $F: \mathcal{D} \rightarrow \mathcal{Q}$ is trivially lax, and any (ordinary) natural transformation $\alpha: F \Rightarrow G$ between functors is trivially (op)lax. The set of natural transformations between two functors $F, G: \mathcal{D} \rightarrow \mathcal{Q}$ is a sub-sup-lattice of both the sup-lattices $\text{Lax}(F, G)$ and $\text{OpLax}(F, G)$ (it is their intersection).

In what follows, $\Delta_A: \mathcal{D} \rightarrow \mathcal{Q}$ denotes the constant functor at the object $A \in \mathcal{Q}$ (on whatever category \mathcal{D}). For an arrow $k: A \rightarrow B$ in \mathcal{Q} the constant transformation from Δ_A to Δ_B will be denoted as Δ_k .

Definition 8.1 *Let \mathcal{D} be a small category, and \mathcal{Q} any quantaloid. For a lax functor $F: \mathcal{D} \rightarrow \mathcal{Q}$ a lax cone over F consists of an object $L \in \mathcal{Q}$ and a lax transfo $\pi \in \text{Lax}(\Delta_L, F)$. Such a lax cone (L, π) is the (necessarily essentially unique) lax conical limit of F if it is universal: for all $A \in \mathcal{Q}$ there is an isomorphism¹⁵ of sup-lattices induced by composition with $\pi: \Delta_L \Rightarrow F$,*

$$\mathcal{Q}(A, L) \xrightarrow{\sim} \text{Lax}(\Delta_A, F): k \mapsto \pi \circ \Delta_k. \quad (15)$$

¹⁵Actually the definition of ‘‘lax (co)limit’’ in a general bicategory asks only for an *equivalence*, and not for an isomorphism. But an equivalence between antisymmetric orders is always an isomorphism, so we put that right away in this definition.

Lax cocone *and* lax conical colimit *are the dual notions*: a lax cocone on F is an oplax transfo $\sigma \in \mathbf{OpLax}(F, \Delta_C)$, and it is the lax colimit if it is universal.

So a lax functor $F: \mathcal{D} \rightarrow \mathcal{Q}$ admits a lax limit (lax colimit) in \mathcal{Q} if and only if $F^{\text{op}}: \mathcal{D}^{\text{op}} \rightarrow \mathcal{Q}^{\text{op}}$ admits a lax colimit (lax limit) in \mathcal{Q}^{op} —this is the duality between limits and colimits.

In general, for an ordinary functor $F: \mathcal{D} \rightarrow \mathcal{Q}$, the limit on F is not necessarily its lax limit: whereas any cone $\alpha \in \mathbf{Nat}(\Delta_L, F)$ is trivially also a lax cone, it is not true that the universal property for such an α to be a *limit* implies the universal property for α to be a *lax* limit. But in some cases lax limits do coincide with ordinary ones. (And by duality we can apply the result to lax colimits, of course.)

Proposition 8.2 *Suppose that, for some lax functor $F_1: \mathcal{D}_1 \rightarrow \mathcal{Q}$ and some (ordinary) functor $F_2: \mathcal{D}_2 \rightarrow \mathcal{Q}$ into a quantaloid \mathcal{Q} , for all $X \in \mathcal{Q}$ there is a sup-isomorphism*

$$\mathbf{Lax}(\Delta_X, F_1) \xrightarrow{\sim} \mathbf{Nat}(\Delta_X, F_2) \tag{16}$$

which is natural in X . Then some $\pi \in \mathbf{Lax}(\Delta_L, F_1)$ is the lax limit of F_1 if and only if $\pi' \in \mathbf{Nat}(\Delta_L, F_2)$, the image of π under the isomorphism above (taking $X = L$), is the limit of F_2 .

Proof : To say that the functor $F_2: \mathcal{D}_2 \rightarrow \mathcal{Q}$ has limit $\pi' \in \mathbf{Nat}(\Delta_L, F_2)$ is to say that there are bijections

$$\beta'_X: \mathcal{Q}(X, L) \xrightarrow{\sim} \mathbf{Nat}(\Delta_X, F_2): f \mapsto \pi' \circ \Delta_f$$

defining an isomorphism of the \mathbf{Set} -valued functors $\mathcal{Q}(-, L)$ and $\mathbf{Nat}(\Delta_-, F_2)$ on (the underlying category of) \mathcal{Q}^{op} in \mathbf{CAT} ; and $\pi' = \beta'_L(1_L)$. However, not only is each $\mathbf{Nat}(\Delta_X, F_2)$ a sup-lattice, $\mathbf{Nat}(\Delta_-, F_2)$ also preserves suprema of \mathcal{Q} -arrows; it is thus a \mathbf{Sup} -valued homomorphism on \mathcal{Q}^{op} . Moreover, the natural bijections above – since they are induced by composition in \mathcal{Q} – always preserve suprema. Therefore, F_2 has limit π' if and only if $\beta': \mathcal{Q}(-, L) \Rightarrow \mathbf{Nat}(\Delta_-, F_2)$ is an isomorphism of \mathbf{Sup} -valued homomorphisms on \mathcal{Q}^{op} in \mathbf{QUANT} .

On the other hand, to say that the lax functor $F_1: \mathcal{D}_1 \rightarrow \mathcal{Q}$ has lax limit $\pi \in \mathbf{Lax}(\Delta_X, F_1)$, is to say that there are sup-isomorphisms

$$\beta_X: \mathcal{Q}(X, L) \xrightarrow{\sim} \mathbf{Lax}(\Delta_X, F_1): f \mapsto \pi \circ \Delta_f$$

defining an isomorphism $\beta: \mathcal{Q}(-, L) \Rightarrow \mathbf{Lax}(\Delta_-, F_1)$ of \mathbf{Sup} -valued homomorphisms on \mathcal{Q}^{op} in \mathbf{QUANT} ; and $\pi = \beta_L(1_L)$.

The result above then follows by composition of isomorphisms of \mathbf{Sup} -valued homomorphisms on \mathcal{Q}^{op} in \mathbf{QUANT} . \square

Two important examples

A set-indexed family $(A_i)_{i \in I}$ of objects in a quantaloid \mathcal{Q} can be identified with (the image of) the functor $F: I \rightarrow \mathcal{Q} : i \mapsto A_i$ whose domain is the index-set regarded as discrete category.

Proposition 8.3 *For a set-indexed family $(A_i)_{i \in I}$ of objects in a quantaloid \mathcal{Q} , the following are equivalent:*

1. $(A_i)_{i \in I}$ has a limit (i.e. product) in \mathcal{Q} ;
2. $(A_i)_{i \in I}$ has a colimit (i.e. coproduct) in \mathcal{Q} ;
3. $(A_i)_{i \in I}$ has a lax limit in \mathcal{Q} ;
4. $(A_i)_{i \in I}$ has a lax colimit in \mathcal{Q} ;
5. there exist an object A and arrows

$$(A \xrightarrow{p_i} A_i \xrightarrow{s_i} A)_{i \in I}$$

in \mathcal{Q} such that, for all $i, j \in I$, $p_j \circ s_i = \delta_{A_i, A_j}$ and $\bigvee_{i \in I} (s_i \circ p_i) = 1_A$.

The cone $(p_i: A \rightarrow A_i)_{i \in I}$ is then the (lax) limit of the given family, and the cocone $(s_i: A_i \rightarrow A)_{i \in I}$ is its (lax) colimit. For each $i \in I$ the coprojection $s_i: A_i \rightarrow A$ is left adjoint to the projection $p_i: A \rightarrow A_i$.

Proof : The equivalence $(1 \Leftrightarrow 2 \Leftrightarrow 5)$ is well-known. $(1 \Leftrightarrow 3)$ and $(2 \Leftrightarrow 4)$ follow from 8.2: because the diagram $F: I \rightarrow \mathcal{Q} : i \mapsto A_i$ is discrete, any lax cone on F is in fact an ordinary cone; and any lax cocone is an ordinary cocone. That is to say, in this particular case we have for any object $A \in \mathcal{Q}$ that $\text{Nat}(\Delta_A, F) = \text{Lax}(\Delta_A, F)$ and $\text{Nat}(F, \Delta_A) = \text{OpLax}(F, \Delta_A)$. The adjunctions $s_i \dashv p_i$ hold since $1_{A_i} = p_i \circ s_i$ and $s_i \circ p_i \leq 1_A$. \square

As usual, we will refer to limits-colimits (in a quantaloid \mathcal{Q}) as *direct sums* and we write them as $\oplus_i A_i$.

A monad in a quantaloid \mathcal{Q} is an endo-arrow $\widehat{\mathcal{A}}^t$ such that $t \circ t \leq t$ and $1_A \leq t$. It can be identified with (the image of) a lax functor $F: \text{Ob} \rightarrow \mathcal{Q} : * \mapsto A, 1_* \mapsto t$. Here Ob stands for the “generic object”: the category with one object $*$ and one arrow 1_* . On the other hand, $\widehat{\mathcal{A}}^t$ is a diagram in \mathcal{Q} , thus (the image of) an ordinary functor $F': \text{Ar} \rightarrow \mathcal{Q} : *_1 \mapsto A, *_2 \mapsto A, \alpha \mapsto t$. Now Ar stands for the “generic arrow”: the category with two objects, $*_1$ and $*_2$, and exactly one arrow that is not an identity, $\alpha: *_1 \rightarrow *_2$.

Proposition 8.4 *For a monad $\widehat{\mathcal{A}}^t$ in a quantaloid \mathcal{Q} , the following are equivalent:*

1. $\widehat{\mathcal{A}}^t$ has a limit (i.e. $t, 1_A: A \rightrightarrows A$ have an equalizer) in \mathcal{Q} ;

2. \widehat{A}^t has a colimit (i.e. $t, 1_A: A \rightrightarrows A$ have a coequalizer) in \mathcal{Q} ;
3. \widehat{A}^t has a lax limit in \mathcal{Q} ;
4. \widehat{A}^t has a lax colimit in \mathcal{Q} ;
5. there exist an object B and arrows

$$B \xrightarrow{p} A \xrightarrow{s} B$$

in \mathcal{Q} such that $p \circ s = t$ and $s \circ p = 1_B$.

If the above is the case for the given monad t , then $p: B \rightarrow A$ is actually its (lax) limit, and $s: A \rightarrow B$ its (lax) colimit. And the coprojection $s: A \rightarrow B$ is left adjoint to the projection $p: B \rightarrow A$.

Proof: $(1 \Leftrightarrow 2 \Leftrightarrow 5)$ is well-known for idempotents in a category, so in particular applies to monads in a quantaloid (it is immediate that a monad in \mathcal{Q} is an idempotent). $(1 \Leftrightarrow 3)$ and $(2 \Leftrightarrow 4)$ follow from 8.2: because $1_A \leq t$, it is the same to give a lax cone on $F: \mathbf{Ob} \rightarrow \mathcal{Q}$ as to give an ordinary cone on $F': \mathbf{Ar} \rightarrow \mathcal{Q}$; and lax cocones on F coincide with cocones on F' . More precisely, we have for any object $X \in \mathcal{Q}$ identical sup-lattices $\mathbf{Nat}(\Delta_X, F') = \mathbf{Lax}(\Delta_X, F)$ and $\mathbf{Nat}(F', \Delta_X) = \mathbf{OpLax}(F, \Delta_X)$. The adjunction $s \dashv p$ follows because $1_A \leq t = p \circ s$ and $s \circ p = 1_B$. \square

The lax limit of a monad \widehat{A}^t in a 2-category is called the *object of t -algebras*, or the *Eilenberg-Moore object* for t , and often written as A^t . And the lax colimit is the *object of free t -algebras*, or the *Kleisli object*, written A_t . In a quantaloid \mathcal{Q} , A^t is isomorphic to A_t as soon as one (and thus also the other) exists: “every t -algebra is free”! When \mathcal{Q} admits (free) algebra objects for all of its monads, we will say that *all monads in \mathcal{Q} split*.

Universal property of the distributor calculus

For the following we refer also to [Betti *et al.*, 1983; Carboni *et al.*, 1987].

Given a quantaloid \mathcal{Q} , there is a quantaloid $\mathbf{Matr}(\mathcal{Q})$ of “matrices with elements in \mathcal{Q} ”, with:

- objects: \mathcal{Q}_0 -typed sets¹⁶;
- arrows: for two objects $(X, t), (Y, t)$, an arrow $\mathbb{M}: (X, t) \rightarrow (Y, t)$ is a *matrix* of \mathcal{Q} -arrows $\mathbb{M}(y, x): tx \rightarrow ty$, one for each $(x, y) \in X \times Y$;
- two-cells: for $\mathbb{M}, \mathbb{N}: (X, t) \rightrightarrows (Y, t)$, $\mathbb{M} \leq \mathbb{N}$ when $\mathbb{M}(y, x) \leq \mathbb{N}(y, x)$ for all x, y ;

¹⁶Recall that such a \mathcal{Q}_0 -typed set (X, t) is really just a way of writing a small discrete diagram $(tx)_{x \in X}$ in \mathcal{Q} .

- composition: for $\mathbb{M}: (X, t) \rightarrow (Y, t)$ and $\mathbb{N}: (Y, t) \rightarrow (Z, t)$, the elements of $\mathbb{N} \circ \mathbb{M}: (X, t) \rightarrow (Z, t)$ are $(\mathbb{N} \circ \mathbb{M})(z, x) = \bigvee_{y \in Y} \mathbb{N}(z, y) \circ \mathbb{M}(y, x)$;
- identities: the identity matrix $\mathbb{I}_{(X,t)}: (X, t) \rightarrow (Y, t)$ has elements $\mathbb{I}_{(X,t)}(x', x) = \delta_{tx,tx'}$ (“Kronecker deltas”).

Clearly, \mathcal{Q} can be embedded in $\text{Matr}(\mathcal{Q})$: every arrow $f: A \rightarrow B$ in \mathcal{Q} may be viewed as a one-element matrix. We write this embedding as $i_{\mathcal{Q}}: \mathcal{Q} \rightarrow \text{Matr}(\mathcal{Q})$. Obviously, $i_{\mathcal{Q}}: \mathcal{Q} \rightarrow \text{Matr}(\mathcal{Q})$ is a fully faithful homomorphism of quantaloids; it is an equivalence of quantaloids if and only if \mathcal{Q} has all direct sums. Actually, $\text{Matr}(\mathcal{Q})$ itself has all direct sums (so “taking matrices” is an essentially idempotent process), and $i_{\mathcal{Q}}: \mathcal{Q} \rightarrow \text{Matr}(\mathcal{Q})$ describes the universal direct-sum completion of \mathcal{Q} in QUANT.

Given a quantaloid \mathcal{Q} , the following defines a quantaloid $\text{Bim}(\mathcal{Q})$ of “bimodules in \mathcal{Q} ”:

- objects: monads in \mathcal{Q} ;
- arrows: an arrow $b: t \dashrightarrow s$ between monads \widehat{A}^t and \widehat{B}^s is a *bimodule* from t to s , i.e. a \mathcal{Q} -arrow $b: A \rightarrow B$ such that $s \circ b \leq b$ and $b \circ t \leq b$;
- two-cells: put $b \leq c$ in $\text{Bim}(\mathcal{Q})(t, s)$ whenever $b \leq c$ in $\mathcal{Q}(A, B)$;
- composition: the composition $c \otimes_s b: t \dashrightarrow r$ of two bimodules $b: t \dashrightarrow s$ and $c: s \dashrightarrow r$ is $c \otimes_s b = c \circ b$ in \mathcal{Q} ;
- identity: on a monad \widehat{A}^t the identity bimodule is $t: t \dashrightarrow t$ itself.

The “tensor” notation for composition of bimodules helps to remind that the identity on a monad \widehat{A}^t is not 1_A but rather t itself.

An arrow $f: A \rightarrow B$ may be regarded as bimodule from 1_A to 1_B ; denote the corresponding embedding of quantaloids as $j_{\mathcal{Q}}: \mathcal{Q} \rightarrow \text{Bim}(\mathcal{Q})$. Then $j_{\mathcal{Q}}: \mathcal{Q} \rightarrow \text{Bim}(\mathcal{Q})$ is a fully faithful homomorphism of quantaloids which is an equivalence of quantaloids if and only if in \mathcal{Q} all monads split. In the quantaloid $\text{Bim}(\mathcal{Q})$ all monads split (so “taking monads and bimodules” is an essentially idempotent process), actually, $j_{\mathcal{Q}}: \mathcal{Q} \rightarrow \text{Bim}(\mathcal{Q})$ describes the universal split-monad completion of \mathcal{Q} in QUANT.

It is now a matter of fact that, for any quantaloid \mathcal{Q} , $\text{Dist}(\mathcal{Q}) = \text{Bim}(\text{Matr}(\mathcal{Q}))$. Indeed, take for example the definition of “ \mathcal{Q} -category”: such an \mathbb{A} consists of an endo-matrix of hom-arrows $\mathbb{A}(a', a): ta \rightarrow ta'$ on the \mathcal{Q}_0 -typed set (\mathbb{A}_0, t) of objects; these data ought to satisfy, for all $a, a', a'' \in \mathbb{A}_0$,

$$\mathbb{A}(a'', a') \circ \mathbb{A}(a', a) \leq \mathbb{A}(a'', a) \text{ and } 1_{ta} \leq \mathbb{A}(a, a),$$

or equivalently,

$$\bigvee_{a' \in \mathbb{A}_0} \mathbb{A}(a'', a') \circ \mathbb{A}(a', a) \leq \mathbb{A}(a'', a) \text{ and } \delta_{ta,ta'} \leq \mathbb{A}(a', a),$$

or still equivalently, but now in terms of matrices, $\mathbb{A} \circ \mathbb{A} \leq \mathbb{A}$ and $\mathbb{I}_{\mathbb{A}_0} \leq \mathbb{A}$. This says precisely that \mathbb{A} is a monad in $\text{Matr}(\mathcal{Q})$, thus an object of $\text{Bim}(\text{Matr}(\mathcal{Q}))$. (Similar for distributors.)

Consequently we now know the universal property of $\text{Dist}(\mathcal{Q})$: the embedding $k_{\mathcal{Q}}: \mathcal{Q} \rightarrow \text{Dist}(\mathcal{Q})$ which equals $j_{\text{Matr}(\mathcal{Q})} \circ i_{\mathcal{Q}}$ is a fully faithful homomorphism of quantaloids which is an equivalence if and only if \mathcal{Q} has all direct sums and all monads split. $\text{Dist}(\mathcal{Q})$ itself has all direct sums and all monads split (“taking categories and distributors” is an essentially idempotent process); actually, $k_{\mathcal{Q}}: \mathcal{Q} \rightarrow \text{Dist}(\mathcal{Q})$ describes the universal direct-sum-and-split-monad completion of \mathcal{Q} in QUANT .

Having all direct sums and a splitting for all monads, is enough for a quantaloid \mathcal{Q} to admit all lax (co)limits.

Proposition 8.5 *For any quantaloid \mathcal{Q} , the following are equivalent:*

1. \mathcal{Q} has direct sums and all monads split;
2. \mathcal{Q} has all lax limits;
3. \mathcal{Q} has all lax colimits;
4. for any lax functor $F: \mathcal{D} \rightarrow \mathcal{Q}$ there exist an object L and arrows

$$(L \xrightarrow{p_D} FD \xrightarrow{s_D} L)_{D \in \mathcal{D}_0}$$

in \mathcal{Q} such that

$$\bigvee \{s_D \circ p_D \mid D \in \mathcal{D}_0\} = 1_L \text{ and } p_{D'} \circ s_D = \bigvee \{Fd \mid d \in \mathcal{D}(D, D')\}.$$

With notations as in the last sentence, the $(p_D: L \rightarrow FD)_{D \in \mathcal{D}_0}$ form the lax limit of F , and the $(s_D: FD \rightarrow L)_{D \in \mathcal{D}_0}$ its lax colimit; moreover, for every $D \in \mathcal{D}_0$, the coprojection s_D is left adjoint to the projection p_D .

Proof: (2 \Rightarrow 1) and (3 \Rightarrow 1) follow from 8.3 and 8.4.

For (4 \Rightarrow 2) and (4 \Rightarrow 3), first observe that $s_D \dashv p_D$: on the one hand $1_L = \bigvee \{s_D \circ p_D \mid D \in \mathcal{D}_0\} \geq s_D \circ p_D$, and on the other $p_D \circ s_D = \bigvee \{Fd \mid d \in \mathcal{D}(D, D')\} \geq F(1_D) \geq 1_{FD}$. Knowing this, it follows from $p_{D'} \circ s_D = \bigvee \{Fd \mid d \in \mathcal{D}(D, D')\}$ that for every $d: D \rightarrow D'$, $p_{D'} \circ s_D \geq Fd$, hence also $s_D \geq s_{D'} \circ Fd$ and $p_{D'} \geq Fd \circ p_D$. Hence $\pi = (p_D)_D$ is a lax cone, and $\sigma = (s_D)_D$ a lax cocone, on F . As for their universality, we must verify that for any $X \in \mathcal{Q}$ the sup-morphisms

$$\mathcal{Q}(X, L) \rightarrow \text{Lax}(\Delta_X, F): x \mapsto \pi \circ \Delta_x,$$

$$\mathcal{Q}(L, X) \rightarrow \text{Lax}(F, \Delta_X): x \mapsto \Delta_x \circ \sigma$$

are bijective (in which case they are sup-isomorphisms). But a calculation shows that their respective inverses are

$$\pi' = (p'_D)_D \mapsto \bigvee \{s_D \circ p'_D \mid D \in \mathcal{D}_0\},$$

$$\sigma' = (s'_D)_D \mapsto \bigvee \{s'_D \circ p_D \mid D \in \mathcal{D}_0\}.$$

For (1 \Rightarrow 4), note that a lax functor $F: \mathcal{D} \rightarrow \mathcal{Q}$ determines a \mathcal{Q} -category \mathbb{D} with objects $\mathbb{D}_0 = \mathcal{D}_0$, types $tD = FD$, and hom-arrows $\mathbb{D}(D', D) = \bigvee \{Fd \mid d \in \mathcal{D}(D, D')\}$: the inequalities $\mathbb{D}(D'', D') \circ \mathbb{D}(D', D) \leq \mathbb{D}(D'', D)$ and $1_{FD} \leq \mathbb{D}(D, D)$ hold precisely because F is lax! Since \mathcal{Q} has all direct sums and all monads split, this \mathcal{Q} -category \mathbb{D} must be isomorphic in $\text{Dist}(\mathcal{Q})$ to a one-object \mathcal{Q} -category, call it $*_L$. This means that there exist distributors $\sigma: \mathbb{D} \rightarrow *_L$ and $\pi: *_L \rightarrow \mathbb{D}$ such that $\sigma \otimes_{*_L} \pi = \mathbb{D}$ and $\pi \otimes_{\mathbb{D}} \sigma = 1_L$. Such σ and π are really collections of \mathcal{Q} -arrows

$$\left(L \xrightarrow{p_D := \pi(D)} FD \xrightarrow{s_D := \sigma(D)} L \right)_{D \in \mathcal{D}_0}$$

satisfying

$$\begin{aligned} p_{D'} \circ s_D &= \mathbb{D}(D', D) = \bigvee \{Fd \mid d \in \mathcal{D}(D, D')\}, \\ \bigvee \{s_D \circ p_D \mid D \in \mathbb{D}_0\} &= \bigvee \{s_D \circ p_D \mid D \in \mathcal{D}_0\} = 1_L. \end{aligned}$$
